H Rille, Extraordinary Professor of Dermatology, has been promoted to an Honorary Professorship.—*Lille:* Dr Ausset, *agrégé*, has been appointed to the chair of Therapeutics.—*Naples:* Dr. Raffaele Minervini has been recognised as *privat docent* of External Pathology, Dr. Noè Scalinci as *privat-docent* of Ophthalmology, and Dr. Anacleto Romano as *privat docent* of Electro-therapeutics.

TRAINED NURSES ANNUITY FUND.—A meeting will be held on behalf of the Trained Nurses Annuity Fund at 19, Stratford place, by kind permission of Emily, Lady Ampthill, on Wednesday next, April 27th, at 3 30 P M. Lady Loch will preside and among the speakers will be Mrs. Garrett Anderson, M.D., and Lady Helen Monro Ferguson.

THE STATE CHILDREN'S ASSOCIATION.—The fifth report of the State Children's Association dealing with the years 1901–03 is a document which will repay careful perusal. The association was founded in 1896 and seeks to better the condition of the large number of children dependent on the rates, of whom 60,000 are wholly in charge of the guardians. The objects of the association are: (1) to obtain the dissolution of large aggregated schools, so that the children may be brought up when possible in families or in small groups, where they will be in daily touch with the varied interests and activities of social life; (2) to dissociate the children from all connexion with the workhouse and the officials who have to deal with a pauper class; and (3) to obtain for the State further powers of control over neglected children. Through its Parliamentary committee, by interviews and by memorials, the association has secured attention from the Local Government Board to necessary reforms, not only with regard to boarding out but to many points which concern the welfare of State children generally. The report can be obtained (price 3*d*) from the office of the association, 58, Old Broad-street London, E C, or from Messrs. P. S. King and Son, 2 and 4, Great Smith-street, Westminster, S W.

UNIVERSITY OF OXFORD: SECOND EXAMINATION FOR THE DEGREES OF B M. AND B.CH.—The Board of the Faculty of Medicine gives notice that on and after Trinity Term, 1905, the whole of the regulations under the head IX. Forensic Medicine and Hygiene (see Examination Statutes, pp. 191, 192) will be struck out and the following will be substituted for them—viz.: "IX. Public Health and Forensic Medicine. The examination shall consist of (1) a written paper of three hours, (2) a *vivâ voce* examination. The subjects of the examination will be: Part I, Public Health.—1 *Water.*—Sources of supply. Questions relating to (*a*) quantity, (*b*) quality, (*c*) storage, (*d*) distribution, (*e*) sources of pollution. 2. *Food.*—Diets in relation to age and occupation. Principles involved in estimating the sufficiency and wholesomeness of foods. Dangers due to specifically infective and toxic impurities 3. *Air.*—The chemical and bacteriological examination of air with reference to its effects on health Quantity and quality of air. Natural ventilation. Principles involved in artificial ventilation and warming of air. 4 *Soil.*—Principles involved in the physical, chemical, and bacteriological examination of soil with reference to its influence on health and to the presence of specific causes of disease. Ground and sub soil water. 5. *Dwellings*—Sites and structure. Sanitary arrangements. The dwellings of the poor in towns and rural districts. The methods of the disposal of excreta in town and country. 6. *Hospitals and schools.*—Principles involved in the construction of general, surgical, and isolation hospitals and of schools. 7. *Disinfection*—Ordinary methods of disinfecting rooms, clothing, bedding, and excreta. 8 *Vital statistics*—The elementary interpretation of statistical data relating to births and deaths Effects of age, distribution, density of population, occupation and infectious disease on mortality. 9 *Offensive and dangerous trades.* 10. *Sanitary laws and administration*—A general knowledge will be required of the following: the law relating to the duties of medical officers of health; the relations of the medical officer of health to the general practitioner of medicine; general statutes and regulations relating to the notification and treatment of infectious disease, to the correction of nuisances generally, and of insanitary conditions in houses; the law relating to vaccination. 11. *Infectious disease.*—The prophylaxis against enteric fever, diphtheria, scarlet fever, and small-pox, and the methods to be adopted in preventing the spread of infectious disease. Part II, Forensic Medicine—I. The proceedings of legal tribunals with reference to medical evidence and the conduct of medico-legal investigations. II. The subjects to which medical evidence relates—namely: 1. *Life.*—Expectation of life, life insurance, identity of the living, proofs of criminal violence, general nature of injuries. 2 *Death.*—Signs and modes of death, time of death, death from natural causes, death by violence, accident, poisoning (including poisoning by gases), starvation, asphyxia. 3. *Birth and reproduction*—Conception and gestation, living and still-birth, criminal abortion, impotence, sterility, violation, unnatural offences. 4. *Lunacy.*—The laws relating to lunacy."

THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN—The first section of the new buildings of this hospital was opened for inspection by the press on April 20th. At present, however, only the out-patient department is apparently far enough advanced for use. When fully completed the new buildings will contain provision for about 200 beds with a separate nurses' home. The portion of the hospital now in progress provides for about 100 beds, and the out-patient department, which occupies the whole of the lower ground floor, is approached from Waterloo-road with separate entrances and exits. The ground floor contains the administrative offices, with accommodation for secretary, committee, matron, resident medical staff waiting rooms, hall and entrance porch, situate at the corner of Waterloo-road and Stamford-street. The first, second, and third floors are devoted to the wards. Each ward has an open balcony facing Waterloo-road, with separate sister's room and ward scullery. The bath rooms and sanitary offices are separated by a ventilated corridor on each floor. Provision is made for a day room on the first floor, an isolation ward on the second floor, and an operating theatre on the third floor. The fourth floor is reserved for the kitchen offices and bedrooms for the staff. A hydraulic patients' lift and service lifts from top to bottom of the building are provided. The floors are of fire resisting construction throughout. Hydrants with fire-hose will be attached to each landing and an iron escape staircase will be provided outside with exits from every floor. The heating will be by hot water, and electric light will be provided throughout. The front of the new buildings is of red brick and terra-cotta. The corner entrance porch is of glazed ware, the cost of which is being defrayed by Messrs. Doulton and Co as a gift to the hospital. The contractors are Messrs. Holliday and Greenwood, Limited, and the architects are Messrs. Waring and Nicholson of 38, Parliament-street, London, S.W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Another Weights and Measures Bill

A BILL introduced by Mr. BOUSFIELD to secure greater uniformity in the administration of the law relating to weights and measures has been read a second time in the House of Commons and referred to the standing committee on law. It will be recollected that a Bill for the introduction of the metric system of weights and measures was presented in the House of Lords some six weeks ago. In the interval it has been read a second time and considered and amended in committee but an incident that occurred in the second reading debate of the Bill "to secure greater uniformity" seems to foreshadow its fate when it reaches the Lower Chamber. In the fourth section of Mr. BOUSFIELD'S Bill it was proposed that after Jan. 1st, 1908, troy weight and apothecaries' weight should be abolished in favour of the metric system. Several members approved of this. It was stated, indeed, that 20 per cent. of the Members of the House were willing to support the introduction of the metric system But as the debate proceeded it became clear that the retention of the section would wreck the Bill and Mr. BOUSFIELD was compelled to promise that in committee he would withdraw the proposal. Mr. GERALD BALFOUR, speaking later, said he was glad to learn of this decision. It was a wise one and he ventured to think that the provision ought never to have been introduced into the Bill at all. The fringe only of the question was touched and it raised very great difficulties without solving them. It certainly would have raised against the Bill the opposition of those trades which were more directly concerned with the tr [illegible] and if the promoters had insisted [illegible] the Bill he would have felt bound [illegible] Government.

Tuberculosis in Animals.

Another Bill which has been read a second time during the week and referred to a committee deals with the question of tuberculosis in animals. The promoters' contention is contained in these words:

"Whereas it frequently happens that it is impossible to detect the presence of tuberculosis in a living animal from its outward appearance and yet such disease may exist to an extent which may justify the condemnation of the carcass after slaughter as unfit for human food, it is expedient to make provision for compensating the owner." From the medical point of view three of the speeches were interesting. Sir Herbert Maxwell, who presided over the Royal Commission which reported six years ago, complained that nothing had been done to give effect to the recommendations of that Commission. If the question of tuberculous disease in cattle had been properly grappled with in this country as it had been in certain continental States any grievance would, in his opinion, have been removed and the question of compensation would not have arisen. It was with a feeling akin to shame that they must contemplate what had been done in coping with tuberculosis successfully and practically and with the concurrence of the people in a small State like Denmark, while no attempt was made in this country to stamp out this most destructive disease. Dr. Farquharson pointed out that it was a very serious fact that while consumption among grown persons had decreased the same disease among children was largely increasing and the problem was whether this was not due to tuberculous milk, and Dr. Hutchinson protested against the attempts to stop the Bill which was, in his opinion, for the benefit of the public health.

Superannuation of Irish Poor-law Medical Officers.

Mr. T. W. Russell has brought in a Bill to provide superannuation for Poor-law medical officers in Ireland.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 13TH.

Vivisection of Dogs.

Five minutes before midnight Sir Frederick Banbury moved in a sentence the following motion: "That in the opinion of this House no operations for the purposes of vivisection should be performed on dogs." As was inevitable in the circumstances the proposal was "talked out."

An Error of Judgment.

Mr. Griffith Boscawen asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the action of Dr. Tierney, J.P., in adjudicating at petty sessions at Clones in cases where he had already acted as medical adviser to, and had accepted fees from, one of the parties; whether a specific case was brought before the Lord Chancellor on Jan. 2nd last; and, if so, whether any notice had been taken of Dr. Tierney's conduct.—Mr. Wyndham replied: This case was brought to the notice of the Lord Chancellor who upon consideration of all the circumstances arrived at the conclusion that official action in the matter was not called for. Steps were taken, however, to convey to the justice named an intimation that the Lord Chancellor considered he had been guilty of an error of judgment in adjudicating in the case in question.

Medical Officers in the Highlands.

Mr. Cathcart Wason asked the Secretary for Scotland whether he would say what system, if any, was adopted by parish councils in the Highlands and Islands of Scotland to acquaint the medical officer of the sickness of paupers, more especially those situated at a considerable distance from his residence; whether the rules as to medical relief of the poor were strictly adhered to by parish councils in remote parishes in the Highlands and Islands of Scotlands, or whether these local bodies were permitted by the Local Government Board to place limitations on them to suit the convenience of the general public, and, if so, whether the Board would take steps to satisfy itself that a laxity with regard to its rules was to the advantage of the paupers; and whether the medical officers were required to visit the houses of paupers throughout the parish at short intervals to ascertain if the paupers were ill, or whether it was the duty of inspectors of poor to intimate to the medical officers when the paupers were requiring medical and surgical attention. Mr. Graham Murray replied: The matters touched upon in the question of the honourable Member are dealt with in the report (already submitted to the House) of the Departmental Committee appointed by the Local Government Board for Scotland to inquire into the system of Poor-law medical relief, &c. That report will shortly be available and I beg to refer the honourable Member to the recommendations contained in it.

The Plague in India.

Sir Walter Foster asked the Secretary of State for India whether he could give the number of deaths from plague in India and the Bombay and Bengal districts respectively for the four weeks ending March 26th.—Mr. Brodrick replied: Except as regards the Bombay Presidency the returns of plague deaths in India received up to to-day do not go beyond the week ended March 19th. The totals for the three weeks ended on that date are 13,187 for Bengal, 24,390 for the Bombay Presidency, and 102,962 for the whole of India, including the above. The number of plague deaths in the Bombay Presidency alone during the month of March was 35,416.

THURSDAY, APRIL 14TH.

The Plague at Hong-Kong.

Answering Sir Walter Foster Mr. Lyttelton said: According to the weekly telegraphic reports from Hong-Kong on the subject, which are regularly communicated to the press as soon as received, there have been 11 cases of plague and 11 deaths at Hong-Kong this year up to April 9th. I have received no detailed report as to the occurrence of plague during the current year but I have given instructions that a report of the acting medical officer of health on the epidemic of plague during the first seven months of last year, which has just been received, should be sent to the honourable Member.

Inoculation for Plague.

Sir John Rolleston asked the Colonial Secretary whether, in view of the results of serum inoculation for plague in India, he would prohibit the use of plague serum in Johannesburg.—Mr. Lyttelton replied: I am not prepared to interfere with the local medical authorities in this matter and I am not aware of any reasons for the suggested prohibition of the use of plague serum to which no objection is taken by my medical advisers.

Adulterated Spirits.

Mr. MacVeagh asked whether the attention of the Government had been called to a recent decision of the Justiciary Appeal Court o Scotland declaring it illegal to describe and to sell as brandy a mixtur of patent spirits and brandy and upholding a conviction by th Sheriff Court of Hamilton under the Sale of Food and Drugs Acts fo this offence; whether they were aware that the officers of excis and customs were compelled by their regulations to allow, i the Government bonded warehouses, German spirit to be labele as brandy and English spirit as Scotch whisky, and whethe such legislation would be promoted or such alterations in the excis and customs regulations made as would render it impossible for thes frauds to be perpetrated under official supervision. Mr. Cavendish replied that the regulations of the Boards of Customs and Inlan Revenue merely prescribed that revenue officers were not to concern themselves in any way with labels placed on spirits issued from bon for home consumption beyond seeing that the labels did not contain any expression implying official supervision. It was not possible unde the rules that German spirit should be labeled in bond as whisky.

MONDAY, APRIL 18TH.

Treatment of Lunatics.

Mr. Sloan asked the Chief Secretary to the Lord Lieutenant o Ireland whether his attention had been called to the practice of takin lunatics to the workhouses without first having them certified by medical practitioner or examined by a magistrate as prescribed by law and, if so, whether he would say in what circumstances it wa permissible to admit such cases without the necessary safeguards t the safety of the persons; and whether instructions would be give for the carrying out of the law in this respect?—Mr. Wyndham replied A person of unsound mind who is *primâ facie* destitute is entitled t be admitted to a workhouse. It is not legally necessary that he sha be certified by a medical practitioner or examined by a magistrat before admission. But such a person may, after admission, be tran ferred to a lunatic asylum if the circumstances justify the transfer.

Deaf and Dumb Children.

Mr. Clancy asked the Chief Secretary to the Lord Lieutenan of Ireland whether he meant to deal this session with the question o extending to Ireland the provisions regarding deaf and dumb childre which have been in force in England for several years past and unde which a sum of £37 090 for deaf, blind, and defective children i England has been placed on the Estimates for the current year, whil no grant is made for such a purpose in Ireland.—Mr. Wyndha replied: I hope to be able to deal with this matter by legislatio during the present session but I cannot at present give a pledge.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institution and others possessing information suitable for this column, ar invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of eac week, such information for gratuitous publication.*

Abram, G. Stewart, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Junior Assistant Physician to the Roya Berkshire Hospital.

Adam, J. Wilson, M.B., C.M. Glasg., has been appointed Medica Physician to the Aberdeen Dispensary.

Anderson, C. A., M.B., M.S. Edin., has been appointed Assistant Hous Surgeon to the Portsmouth Hospital.

Burnet, James, M.A., M.B., M.R.C.P. Edin., has been appointe Registrar to the Royal Hospital for Sick Children, Edinburgh.

Cowie, James M., M.D. Aberd., D.P.H., has been appointed Medica Officer of Health and Public Analyst for the County Borough o Burton-upon-Trent.

Ellis, L. Erasmus, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond L.S.A., has been appointed Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester-square, London, W.C.

Glegg, R. Ashleigh, M.B., D.P.H. Edin., has been appointed Assistant Medical Officer of Health of Leith, and Residen Physician to Leith Public Health Hospital.

Lloyd, William, F.R.C.S., has been appointed Surgeon in Charge o the Nose, Ear, and Throat Department, St. Pancras and Grea Northern Dispensary, W.C.

Moir, D. R., M.A., M.B. Aberd., has been appointed Visiting Surgeon to the Hull and Sculcoates Dispensary.

Pentreath, C. H. R., B.A., M.B., B.C. Cantab., has been appointe Resident Medical Superintendent of the Government Sanatorium for Consumption, Cambridge, New Zealand.

Wall, Cecil, M.A., M.D. Oxon., M.R.C.P. Lond., has been appointed Honorary Physician to the Poplar Hospital.

Vacancies.

For further information regarding each vacancy reference should b made to the advertisement (see Index).

Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

Brighton, Hove, and Sussex Throat and Ear Hospital, Church-street, Queen's-road, Brighton.—Honorary Consulting Surgeon, also Honorary Surgeon.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon. Salary £80, with board, lodging, and washing.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Pathologist. Salary £300 a year.

CHELSEA HOSPITAL FOR WOMEN, Fulham road, S W.—Clinical Assistant

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark —House Physician. Also House Surgeon. Salary £80 respectively, with board, residence, and washing.

SHA[illegible] W., the [illegible]

MARRIAGES.

PARAMORE—GODSON.—On April 14th, at Christ Church, Woburn-square, W.C, Richard Horace Paramore, M B. Lond., M R C S., L R C P., to Lilian Mabel, the youngest daughter of the late Rev Edwin Godson, M A

RICE-CARROLL —On April 12th, at Mitchelstown, W. Rice, M B, B Ch, B A O. R U I, of Curraghmore, Fermoy, co. Cork, to Catherine, youngest daughter of the late Michael Carroll of Doneraile.

DEATHS.

FAULKNER [illegible] M R C [illegible]

MASON.—[illegible] year, [illegible] upon Trent.

MORICE.—On Feb 20th, 1904, at Greymouth, New Zealand, Charles Lloyd Morice, M R C S., L S A.

THOMPSON —On April 18th, at Wimpole-street, W., Sir Henry Thompson, Bart., F.R C S., in his 84th year

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A COURTEOUS PRIEST.

WE received a few days ago a letter from someone signing himself (Rev.) Montague Fowler and writing from 41, Wilton-crescent, S.W. The letter inquired from us information about the books which treated of certain diseases To this we replied that we made it an almost invariable rule never to answer questions with regard to the treatment of disease unless they were addressed to us by a medical man. The Rev. Montague Fowler acknowledged our letter in the following terms.—

> 41, Wilton-crescent, S W.
>
> DEAR SIR,—I am in receipt of your letter of to-day's date, which has nothing to do with the question I asked you—to which, I gather, you are unable to give me an answer. I am sorry to have troubled you, but I was given to understand that you were *au courant* with the standard medical works.
>
> Yours fy.,
> MONTAGUE FOWLER.

We are asked constantly by members of the public to assist them to find in medical literature the way to treat disease. We, of course, tell such inquirers to consult their medical men, because they will [illegible] them. We do not give [illegible] supersede medical men [illegible] position thus taken up [illegible] of our correspondents, [illegible] r to do so. We do not know this gentleman, he is not a medical man, and has no claim on our time. As he has been unable to understand our previous communication to him we will strive this time to make ourselves particularly clear. If the Rev. Montague Fowler wants medical advice let him seek it from his medical man, and pay for it.

"NOTHING ILLEGAL ENTERTAINED."

WE have received from a correspondent the circular which follows:

> Mrs. B. S. Arons,
> 27, Manchester Road, Blackpool.
>
> NOTHING ILLEGAL ENTERTAINED, strict confidence, no injurious drugs used. Advice Free.—State your case clearly.—Send full postal address. Stamped addressed envelope for reply.
>
> Womans' Remedies made by a woman for women.
>
> Female Pills.
>
> Removes Irregularities, Safe, Reliable The Pills are a never failing Remedy in the most troublesome disorders, in most cases where a woman has taken these pills, for about a week before and after, each month, they have kept her quite regular. Should also be taken during the month. They will purify the system, stimulate the blood and put a healthy colour in the cheeks and skin. They may be taken with perfect safety and success, by the young unmarried female suffering from Amenorrhea, equally so in the case of Females of mature years in the change of life.
>
> 2/9. PRICE 2/9 PER BOX. POST FREE TO ANY ADDRESS. 2/9.
>
> Female Mixture.
>
> The Safest and Surest Mixture for Females. Highly recommended by Ladies in all parts of the Empire It is essential that the Mixture should be taken, and should be persevered with until it has thoroughly established the natural flow (state time of supression)
>
> This Mixture has great strengthening and invigorating properties which act directly on the Female Organs Price 4/6 per Bottle, Extra Strong and Larger Size 6/- sent post paid securely [illegible] together quite harm- [illegible] you derive benefit.— [illegible] al Study and if you have been "gulled by Chemists and Quacks, don't despair, give my Pills and Mixture a fair trial, have relieved and given happiness [illegible] never be used, unnatural and [illegible] ncer and Tumours. [illegible]
>
> Barrenness in Women, in cases where a Woman, has not had [illegible] tting—But [illegible]
>
> All Cases and Diseases, treated with GREATEST CONFIDENCE.

The gentleman who has sent us the document asks "Can nothing be done to stop such frauds?" We confess that we do not know what are the principles upon which the police act. This woman is clearly advertising for clients whom she may assist in their desire to procure abortion upon themselves. The almost invariable cause of the suppression of menses in a young woman is pregnancy. What are "indiarubber goods" used for save to prevent pregnancy? And the woman herself puts forward her stuff as a substitute for "indiarubber goods." That Mrs. Arons's pure herbal remedies would not act as ecbolics is probable, but it is certain that she expects gullible females to think differently that they may invest 4s. 6*d*. or 6s. with her for some rubbish the initial cost of which is probably 1*d*. or 2*d* We do not know why the police ignore the manœuvres of Mrs. Arons and her like, but when we remember that until recently many reputable newspapers actually inserted the advertisements of such people, and note that some even do so still, we can understand that the authorities are puzzled.

HOLMAN TESTIMONIAL FUND.

The following further list of contributions has been forwarded to us by the honorary treasurer of this fund, Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., by whom or by Mr. W. A Berridge, Oakfield, Redhill, Surrey, subscriptions will be received:—

THE ROYAL METEOROLOGICAL SOCIETY.

At the monthly meeting of the Royal Meteorological Society held on April 20th at the Institution of Civil Engineers, Great George-street, Westminster, a paper, which was of some medical interest, was read by Mr. W. L. Dallas on the Variation of the Population of India compared with the Variation of Rainfall in the Decennium 1891–1901. The author showed that during the four years 1891–95 the rainfall was generally normal or heavy over nearly the whole country, and during the six years 1895–1901 the rainfall was greatly deficient. During the former or "wet" period the rainfall was deficient over Upper Burma and Madras, was normal over the remainder of Burma, Assam, Bengal, and the west coast of the Peninsula, and was excessive elsewhere; while during the latter or "dry" period the rainfall was again deficient over Upper Burma, normal or excessive over the remainder of Burma, Assam, Bengal, the United Provinces, the North-West Frontier Province, and the South of Madras, and was deficient elsewhere, most so over Rajputana and neighbouring areas. The general census of India on March 1st, 1901, showed the total population to be 293,475,477, which, excluding the territories not included in the 1891 census, was an increase of only 1·3 per cent. The population had thus failed to increase according to the normal rate during the decade. Part of this failure was no doubt due to epidemics. The author, however, shows that there is an unmistakeable relationship between the variations of the population and the variations of rainfall during the dry years. The area within which the most serious decrease of population occurred coincides almost exactly with the area of greatest deficiency of rainfall.

PUS IN THE MOTIONS OF A CHILD.

To the Editors of The Lancet.

Sirs [illegible] hould be very grateful if any of the readers of The Lanc[illegible] throw light on the following case. The patient is a g[illegible] of age, who has periodical discharge of pus in the motion[illegible] nth or so. There is absolutely no sign of tuberculous peri[illegible] has never had appendicitis; she does not suffer from [illegible] symptom is an occasional pain described as "[illegible] ing the iliac crest when she runs about; otherwise she is [illegible] in g[illegible]. I may mention that the last time the disc[illegible] us w[illegible] med was after a dose of castor oil given for sligh[illegible] tion, to [illegible] she is subject.

I am, Sirs, yours faithfully,

A Puzzled G.P.

April [illegible]

BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of The Lancet.

Sirs,—I shall be very much obliged if you will give me room to say that I am constantly receiving applications for clothing, &c, and am unable to comply with requests as our wardrobe is empty. For many years I have received and distributed clothing of all sorts and hav been able to afford most useful help to many of the recipients of al from the Fund. Any members of the profession who have clothin with some wear in it to dispose of may send it to me at this addres and I can guarantee that it shall be distributed to the best advantage I have now applications for men's clothing of every description women's clothes and underclothing, children's school clothes (boys an girls), black dresses to start girls in situations, hats, bonnets, jackets and cloaks, evening dress, furs of all sorts, and boots and shoes Everything comes in useful and finds its place and room can be founc for material to make up as wanted. The supply of clothing ha fallen off during the last three years and it has been found difficul to keep abreast of wants. I would particularly ask executors an those who have to deal with the wardrobes of deceased medical me or have a chance of influencing the disposal of the wardrobes o patients to think of their poorer brethren and remember our wants.

I am, Sirs, yours faithfully,

26, Linden-gardens, W., April 19th, 1904. Edward Rist.

DR. J. T. C. CONRY'S DEFENCE FUND.

To the Editors of The Lancet.

Sirs,—Since April 12th, when the amount received was £18 16*s*. 6*d* the following sums have been contributed:—

	£	*s.*	*d.*
Dr. Alexander Davidson	1	1	0
Dr. T. Neville	0	10	6
Sir William Whitla	1	1	0
Dr. H. Macnaughton Jones	1	1	0
Dr. E. S. W. ("A Poor Country Surgeon") ...	0	5	0
Dr. W. Pringle Morgan	1	1	0
Rev. D. J. Forbes	0	10	0
Mr. G. Vere Benson ...	0	2	
Surg.-Gen. C. Sibthorpe	1	1	
Dr. J. T. Higgins	1	1	
A. M O.	0	10	
Dr. T. W. S. Paterson ...	0	10	
Mr. Colin Campbell	0	10	
Dr. Jacob Pickett	0	10	
	£28	12	

We are, Sirs, yours faithfully,

Edwin T. Ensor.

THE REDUCING POWER OF CREATININE ON FEHLING'S SOLUTION.

To the Editors of The Lancet.

Sirs,—On p. 1026 of The Lancet I find that "Research" desires to have reference to some work on this subject. Dr. R. S. Thomson, professor of medicine in Anderson's College Medical School, Glasgow, h worked in this direction.

I am, Sirs, yours faithfully,

F. D.

April 11th, 1904.

A SIMPLE QUESTION.

To the Editors of The Lancet.

Sirs,—May I ask your opinion on the following incident? A hou vacated by a practitioner X is occupied by another practitioner Y. A former patient calls and finding X gone asks where. Y replies: "I don' know" (untrue), and adds, "I am doing his work" (untrue), thereb inducing the patient to take advice and to give a fee. Is this etiquette

Inclosing my card,

I am, Sirs, yours faithfully,

G.P.

April 16th, 1904.

*** No.—Ed. L.

SMOKING IN THE WARDS OF A HOSPITAL.

To the Editors of The Lancet.

Sirs,—Is the medical officer of the local fever hospital of a county borough justified in habitually smoking a pipe whilst making his daily ward visitations and would the sanitary committee of that borough b in order in asking him to discontinue the practice?

I am, Sirs, yours faithfully,

Nicotine.

April 18th, 1904.

*** As far as possible it is useful and right to treat the hospita patient as the private patient is treated, so that, in our opinion, th alleged pipe-smoking habit of the medical officer is inexpedien and ill-mannered.—Ed. L.

◆

The Secretary of the Treherbert Medical Attendance Society.—Th facts given by the correspondents of The Lancet are not traversed The objections to the scheme appear to us to be perfectly valid.

Communications not noticed in our present issue will receive attentio in our next.

During the week marked copies of the following newspaper have been received:—*Eastern Morning News, Aberdeen Fre Press, Sussex Daily News, Dublin Times, Birmingham Post, Surre Advertiser, Notts Guardian, Westminster Gazette, Dublin Expres Bradford Observer, Hereford Mercury, Sanitary Record, Loca Government Chronicle, Mining Journal, Hertfordshire Mercu The Scotsman, Evening News, Surrey Comet, Revue de Chirurgi (Paris), Irish Times, &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

The Oliver-Sharpey Lectures
ON
RECENT STUDIES ON THE TISSUE-LYMPH CIRCULATION.

Delivered before the Royal College of Physicians of London on April 12th and 14th, 1904,

By GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE I.

Delivered on April 12th.

THE LATE PROFESSOR WILLIAM SHARPEY, F.R.S.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—Before proceeding to the subject of this the first of the Oliver-Sharpey lectures I must say a few words in memory of the late Professor Sharpey in whose honour this endowment has been made. This is to me a most grateful duty, for to his vivid and sound teaching I owe a life-long love of physiology and his sterling qualities of mind and heart are to me one of my most cherished memories. Happy the student who had the good fortune to fall under the spell of such a great teacher as William Sharpey undoubtedly was. His lucidity and picturesqueness of style, his directness and simplicity, his happy faculty of illustration, and, withâl, the geniality and goodness of heart which enveloped and adorned all his well-digested teaching, must have deeply impressed and powerfully influenced many generations of students at University College from 1835 to 1873. In those days physiology was waking to the fuller light we now enjoy. Her teachers needed a cautious, trained judgment—such as William Sharpey pre-eminently possessed—rather than the somewhat venturous ways of the discoverer, for there were many alluring lights in the air and the pupil needed, warning as well as teaching. And so the settled dawn of real progress was fostered by William Sharpey and his life-work is now perpetuated and fully developed in our British school of physiology. Hence it seems fitting that in this endowment we should indicate what we conceive to be his rightful place in the modern history of physiology. The aim of this endowment is to foster the application of physiological knowledge to the prevention, alleviation, and cure of disease and the prolongation of life, believing, as we do, that the medicine of the future will become more and more physiological as we understand more clearly the forces of nature. May the duty imposed on this College contribute, in however small degree, to the fruitful realisation of our ideal.

TISSUE-LYMPH CIRCULATION.

I propose to submit to you the results of a study on the circulation of the tissue fluid in man, or, in other words, on the fluid transfers between the blood and the tissues. Apart from its intrinsic physiological interest this subject has important bearings on the practice of medicine.

When I had the honour of delivering the Croonian lectures before this College in 1896 some observations were adduced which pointed to certain inferences in regard to that *terra incognita* in man, the great extravascular circulation. But these inferences were merely suggestions prompted by the incomplete data at my command. Subsequent work enables me to present the results of observation in a somewhat more definite and extended form. Some of the conclusions suggested to me by this inquiry were so unexpected that I was naturally led to repeat my observations in every department of it over and over again and to scrutinise all the facts with more than ordinary diligence. Over 3000 observations have been made in health and disease; but I propose in these lectures to use mainly the physiological material. As I proceed, however, you will readily recognise the drift and bearing of the physiological data on medical work and I will summarise their practical teaching.

METHODS AND APPARATUS.

[Dr. Oliver here described the methods and apparatus[1] employed with certain improvements in the hæmocytometer,[2] hæmoglobinometer,[3] and hæmodynamometer.[4]]

THE EFFECT OF THE INGESTION OF FOOD ON THE TISSUE-LYMPH CIRCULATION.

Elsewhere[5] I have shown that the ingestion of food initiates an interesting series of variations in the blood and blood pressures which culminates in a prolonged wave-like exudation of tissue lymph and that this excitation in the circulatory system recurs with perfect regularity after each meal. Subsequent inquiry has amply confirmed this position.

The digestive variations in the blood pressure.—The ingestion of food invariably raises the arterial blood pressure (Fig. 1). In an hour after a meal it rises 15 or even 20 *millimetres of mercury, then it begins to fall, and in from* two and a half to three and a half hours it become stationary until the next meal or until exercise is taken. The venous pressure after food has been made the subject of more particular study, because of a dip in that pressure occasionally observed, for a very brief period, when the maximum effect of digestion on the circulation is attained—an hour after a meal. In my earlier observations (made in cold weather) I was disposed to think that this temporary fall was more frequently met with than it is. The superficial veins and venules are very sensitive to the influence of cold after a meal, when the rise of the capillary pressure favours the dissipation of heat from the surface of the body. In this way the occasional short dip of venous pressure may be produced, but as a rule the curve of this pressure rises and falls throughout with that of the arterial pressure. It may, I think, be inferred from these facts that the capillary blood pressure follows the same curve of rise and fall after meals, for we know that this pressure is more closely related to the venous than to the arterial pressure and that if both these pressures rise together we may fairly assume that the capillary pressure will also rise. After food the pulse rate also increases and in an hour it may have gained from eight to 15 beats a minute. When the pulse pressure gauge is applied so as to arrest the pulsation of the radial artery (the finger being used as the indicator) the reading becomes cardiometric and is generally increased in an hour after a meal from 15 to 20 millimetres of mercury. Therefore it would seem that digestion very considerably stimulates the heart, augmenting the output and the contractile energy of the ventricle.

FIG. 1.

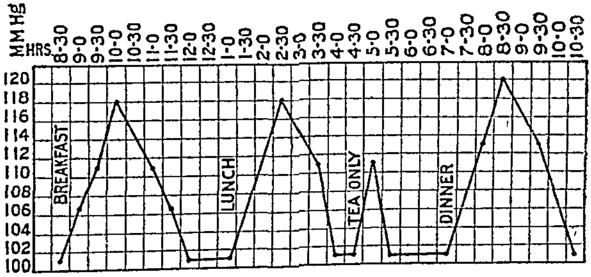

Chart showing rise of arterial pressure after food.

The essential aim of the digestive excitation of the circulatory system is to raise the capillary blood pressure and according to the teaching afforded by my observations this end is attained by the increased activity of the cardiac muscle. But would it still be effected were some substance to be taken with the meal which lowered the arterial pressure by merely dilating the arteries and arterioles and left the raised cardiac action which results from the ingestion of food unimpaired? We should expect to find a great increase in the venous pressure and in the capillary pressure which would still be between two higher pressures. Now this is precisely what happens when 0·065 gramme (one grain) of Witte's peptone is taken with a meal. This remarkable vaso-relaxant, to which I will again refer in the second lecture, does not lower the heart's action, for the blood-pressure gauge gives the same cardiometric rise whether the peptone is added to a meal or not, consequently the reduction of the arterial and arteriolar resistance effected by this substance combined with the digestive cardio stimulation should produce a great rise in the capillary blood pressure. [A chart was here exhibited showing a simultaneous rise of the venous pressure from 20 to 50 millimetres of mercury and fall of the arterial pressure from 100 to 80 millimetres of mercury. Food was taken at 1 P.M. and the maximum venous rise and maximum arterial fall occurred at 3 P.M.] We may therefore infer that we may have a rise in the capillary pressure either with an increase or a decrease of the arterial pressure according as we have cardiac stimulation (as after meals) or vaso-dilation.

DIGESTIVE VARIATIONS IN THE BLOOD.

I have followed three series of alterations in the blood during digestion—namely, in the corpuscles, in the hæmoglobin, and in the specific gravity. As the variations in the chromocytes and in the hæmoglobin are identical they will be taken together.

Digestive variations in the corpuscles and hæmoglobin.—The finger, having been subjected to the compression of the rubber rings, yields blood which shows a progressive rise in the percentages of the corpuscles and of the hæmoglobin until an hour has elapsed, when the increment amounts to from 8 to 10 per cent.; then the percentages gradually fall and they finally settle down to normal in from two and a half to three and a half hours (Fig. 2, A). Should, however, the blood be derived from the finger in the ordinary way (without compression) the successive readings of the blood elements indicate a progressive fall in the percentages which in an hour amounts to from 6 to 8 per cent. when a rise sets in and recovery is eventually established (Fig 2 B).

FIG. 2.

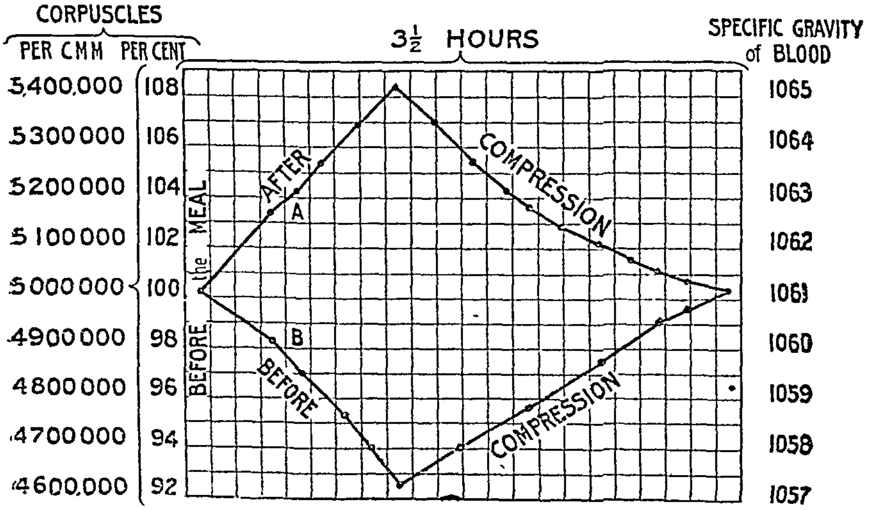

Chart showing the percentages of corpuscles and the specific gravity of the blood before and after compression. Observations made before a meal and at frequent intervals afterwards.

Digestive variations in the specific gravity of the blood.—The blood, as shown by compression of the finger, rises in specific gravity after meals, the rise reaching its maximum point (e.g., from 1061 to 1065) in an hour. The specific gravity then begins to fall, settling down to the initial point at the conclusion of the wave-like disturbance (Fig. 2, A). On the other hand, the blood derived from the finger uncompressed affords a specific gravity which follows the contrary course—that is to say, it falls and then rises (Fig. 2, B). When the digestive disturbance is over the variations in the blood, like those in the circulation, cease and the readings in normal subjects at rest continue to be alike in both samples (before and after compression) until the following meal.

The digestive exudation of tissue lymph.—On reviewing the foregoing data it is obvious that they indicate strictly concurrent events. All the four series of variations follow exactly the same curve. They begin together, they attain their maximum development at the same time, and they simultaneously cease. What is the link which binds them together? If we suppose that the ingestion of food in some way raises the capillary blood pressure which exudes a filtrate of a portion of the liquor sanguinis into the areolar spaces all the changes in the blood which I have described will naturally follow (see Fig. 2). In proportion to the exudation under a rising capillary blood pressure the blood will become more and more concentrated in chromocytes and in hæmoglobin, and inasmuch as its specific gravity mainly depends on the corpuscles the density of the blood will rise *pari passu* with the increased concentration. Then, when the capillary pressure begins to fall, as it does after the acme of the digestive disturbance has been attained, the concentration of the blood diminishes and we may assume that either absorption of the watery elements of the effused lymph overbalances exudation or that the effusion is being returned by the lymphatics to the blood. Now I have shown that none of these alterations in the blood could have been ascertained by the examination of blood derived from the finger in the ordinary way, they only become apparent after the compression of the tissues by the rubber rings which remove the extra-capillary fluid and enable us to obtain the blood undiluted by that fluid. But the progressive readings of the ordinary samples of blood, though valueless, and actually misleading when accepted as independent testimony of blood changes during digestion, become instructive when compared with the readings of samples obtained after compression, for they then afford a measure of the amount of fluid withdrawn from the blood. The differential readings of the hæmocytometer tubes made every 15 minutes after a meal show the greatest divergence and therefore the largest quantity of tissue fluid, just at the time (an hour after a meal) when the digestive blood-pressure wave and the concentration of the blood attain their maximum development. The difference, indicated by the scale on the tubes, will amount to from 15 to 20 per cent.; it will then gradually diminish, and will finally disappear in from two and a half to three and a half hours, and will not reappear until after the next meal or until exercise is taken. The amplitude and duration of the lymph wave are influenced by several conditions, such as the tone of the subject, the bulk and nature of the meal, the use of beverages, rest, or exercise.

Other rhythmical digestive variations.—I will now direct your attention to other physiological variations produced by the ingestion of food, synchronous with the foregoing. For the influence of digestion is not merely confined to alterations in blood pressure, the composition of the blood, and the production of tissue lymph: it is still more far-reaching and a study of these further rhythmical changes will widen our grasp of this interesting subject and enable us to discover the link which binds together all these apparently diverse physiological movements.

The digestive curve of augmented respiratory exchange.—I show you Fredericq's curve of daily variation in the absorption of oxygen. [This chart showed that the absorption of oxygen, which was 4·5 litres when food was taken at 8 30 A M., rose steadily to 5·8 litres at 10 A M. and then fell steadily to 4 6 litres at 1.30 P.M. Food was again taken at 1 30 P M and the absorption of oxygen rose steadily to 6 6 litres at 3 P.M.] You see it follows exactly the line of development and duration of the curves just studied

Other observers (Vierordt, Speck, Berg) besides Fredericq have shown that the intake of oxygen and the output of carbonic acid are greatly stimulated by the ingestion of food.

A rhythmical variation of muscular contractility after food.—Physiology shows that the greater part of the oxidation processes of the body go on in the muscles and that when these are quiescent their metabolic activity merely diminishes and does not cease. But does it vary during intervals of rest? Is it stimulated by digestion? The increased intake of oxygen at that time is somewhat favourable to such a view. But we must remember that the secretory work of the digestive glands will require an augmented supply of oxygen, and, moreover, the process of oxidation appears as a rule to be more closely associated with the katabolic than with the anabolic side of metabolism, with reduction and cleavage of the organic molecule rather than with construction of it and repair, which we know to be the physiological aim of digestion. I have, however, observed some facts which show that very marked alterations do go on in the muscles after meals. These facts came to light while studying the effect of muscular tension on the arterial blood pressure. A short, general tetanic contraction always raises the arterial pressure. This result is mainly due to the compression of the intramuscular vessels produced by the shortening of the fibres of the muscles. This method of testing muscular contractility, however, involves other physiological factors, such as cardiac excitation and a possible variable effect from the vaso-motor condition of the arteries. Cardiac stimulation may, however, be excluded from consideration, as it is common to all the observations, and I have not seen any sufficient evidence to show that the tonus of the arteries materially affects the result. I have invariably found that *the maximum response* in the arterial-pressure rise is produced by quite a moderate degree of muscular contraction, that the results obtained are constant and are trustworthy indications of muscular contractibility,[6] which varies very considerably at different times. The study of these variations is instructive; it has shown that they always follow a certain order, or, when plotted out, a certain curve, as in Fig. 3. You observe that the effect of the muscular tension in raising the arterial pressure diminishes *pari passu* as the effusion of lymph increases and develops again as the lymph disappears. From this fact (which is apparent whenever tissue lymph is thrown out, whether by meals, exercise, or sleep) I conclude that the lymph exuded into the muscular tissue checks the shortening of the muscular fibres and thus the effect of their contraction on the intramuscular vessels is diminished; so the failure to raise the arterial pressure to the same height as before the effusion indicates the amount of the infiltration clogging the contracting fibres.

FIG. 3.

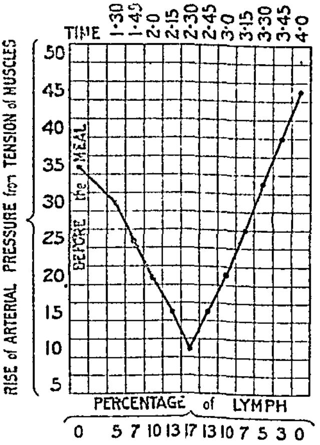

Chart illustrating the effect of muscular contraction on the arterial pressure after a meal. It shows the obstructing effect of tissue lymph and the ultimate gain in contractility.

These observations on the condition of the muscles during digestion, therefore, confirm the teaching as to the outflow and absorption of lymph furnished by the differential examination of the blood. You will note, further, that at the terminatio

a gain in the

tional rise of

pressure produced by muscular tension. This gain (which only becomes evident after the absorption of the lymph) varies from five to 20 millimetres, according to the nature of the food consumed and the need for recuperation. You will find the tension test useful in practice. In those cases in which you observe a rise in the arterial pressure there will be an increased exudation of lymph, for the two facts go together; when the impairment of the muscular contractibility on the arterial pressure will not only confirm your observation of that pressure but will provide you with a ready indication of the amount of tissue lymph. For example:—

TABLE I.

No of case	Arterial pressure.	Muscular contractibility rise of arterial pressure.
1.	148 mm. Hg.	0
	115 " "	10 mm. Hg.
	100 " "	30 " "
2.	135 " "	0
	100 " "	25 mm. Hg.
3.	120 " "	5 " "
	100 " "	40 " "

The observations were made at a time when normally the arterial pressure should be 100 millimetres of mercury. The reduction in pressure was effected by treatment.

The gastric juice curve.—There is also the rhythmical curve expressing the work of the gastric glands, so well worked out by Pawlow, which is synchronous with all the foregoing physiological variations. [A chart was here exhibited showing that the yield of juice rose abruptly in an hour from 0 to 10 cubic centimetres and during the next four hours fell gradually to 0.] All the six concurrent curves of augmented functional activity which I have just described are obviously but the widely diffused effects throughout the organism of a great central movement initiated by the ingestion of food through the agency of the nervous system. How some of these effects are produced and how they may be varied and controlled are questions to which we must now turn.

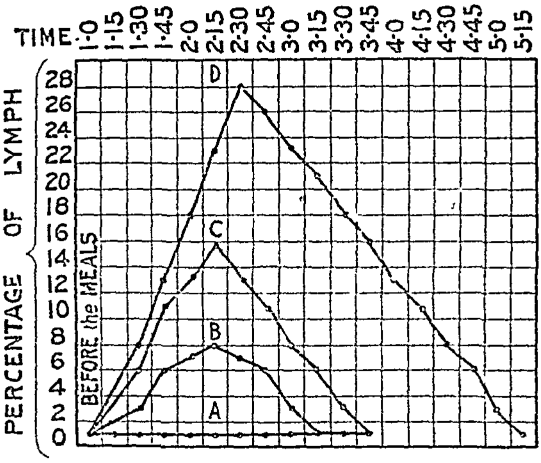
The effects of typical meals on the digestive lymph flow.—Let us now study the digestive curves of lymph exudation produced by four different kinds of meals: First, the ordinary mixed meal containing the usual proportions of animal food, vegetables, and farinacea; secondly, the meat meal, consisting of animal food in various forms, with cheese and butter and a very little toast; thirdly, the vegetable meal with farinaceous puddings, fruit, and cheese; and fourthly, the milk meal, milk, bread, and farinaceous puddings. In each case the fluid supplied was a tumbler of water and the amount of food was merely limited by a feeling of satisfaction. Sugar and salt (two grammes of each) were taken in the same quantity at all the solid meals. The meal was at one o'clock and the same subject was, throughout, submitted to observation. No exercise was permitted for an hour before and after meals, nor until the digestive disturbance had quite subsided. Observations were made just before the meals and every 15 minutes after them. The results are epitomised in the following table (Table II.).

---

no lymph is present (contractility).

addition of salt and more especially by that of salt associated with the physiological products than when taken alone.

FIG. 5.



A, lymph record from purin-free meal. B, purin-free meal with sodium chloride 2·0 grammes. C, purin-free meal with sodium chloride 4 0 grammes. D, purin-free meal with sodium chloride 2 grammes and uric acid 0 016, creatin 0·033, creatinin 0·033, xanthin 0 016, hypoxanthin 0·016, and glycogen 0 048.

It seems to me that these facts demonstrate that such bodies as uric acid, creatin, creatinin, xanthin, glycogen, and sodium chloride perform an important function in nutrition, for during digestion they act as distributers of lymph to all the tissues, an office which the nutrient constituents themselves (proteids, fats, and carbohydrates) are incapable of discharging. As inquiry goes forward it may discover other substances possessing this physiological property associated with our food elements. Nature has, with a wise intent, widely distributed these active chemical agents through most of our food-stuffs and beverages, thus turning even her waste products to the best account, the nutrition of the organism. Unfortunately, man, in his efforts to improve on nature, so often turns these benefactors into malefactors. Besides these lymph factors introduced from without there are supplies of the same materials generated within us. It will be shown, too, that exercise, sleep, and variations of temperature are important physiological conditions for the autogenous supply of tissue lymph. It is not improbable that in some subjects the endogenous production of lymph factors may exceed the physiological average, when an adjustment can only be effected by a limitation of the exogenous supply. But I am here touching the borderland between physiology and pathology, to which I hope to revert in the second lecture.

ABSTRACT OF AN

Address

ON

MEDICAL ETHICS.

Being the Presidential (Valedictory) Address delivered before the Medico-Ethical Association of Manchester on Jan. 27th, 1904,

BY D. LLOYD ROBERTS, M.D. ST. AND., F.R C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL, MANCHESTER; CONSULTING OBSTETRIC PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; AND LECTURER ON CLINICAL OBSTETRICS AND GYNÆCOLOGY AT THE OWENS COLLEGE, MANCHESTER.

IN the course of his introductory remarks Dr. Lloyd Roberts said that the Medico-Ethical Association of Manchester was the first organisation of the kind which was established and that the celebrated "Medical Ethics" of Thomas Percival was written in Manchester rather more than a hundred years ago. He referred briefly to various speculations on the philosophical basis of ethics and proceeded as follows:—

The great function of a medico-ethical association appears to me to be to assist in applying the rule of right in medical matters. It will, therefore, naturally endeavour (1) to impose a wholesome restraint upon the liberty of individual members of the profession in the interest of all, and (2) to assist in passing wise laws in those matters which relate specially to public health and the interests of the profession.

Let me first say a few words upon the restraints which the Medico-Ethical Association of Manchester has imposed upon the conduct of its own members. The chief restraint which finds expression in our laws relates to the prosaic and homely, but by no means unimportant, question of fees. It is as essential for the public as for us that our dignity should be maintained and we give to them the greatest guarantee that they will have honest and trustworthy services in the time of need by showing that we are a self-respecting and a disinterested profession. This society has been performing a public duty by insisting that its members shall claim fair remuneration for services rendered. That our tariff which has been drawn up by the society is a fair one is attested by the fact that it forms the basis of every scale of fees now in existence in this country. Our association has also done much to raise the character of the profession by inculcating a high code of honour in the dealings of members with one another. The laws of this code embody implicitly the hitherto unwritten rules which constitute the etiquette of the profession. This etiquette is indeed only a branch of the salutary discipline which society in general exercises over its individual members, and the restraint which our etiquette places upon those who follow their own supposed interests, regardless of the injury which they may inflict on their brethren, is a wholesome restraint and has been enforced by this society with a due measure of leniency and justice.

Many schemes of social advancement and reform which at the time of their inception were advocated in this very room have already found, and others will yet find, their embodiment in the laws of our country. The question of provident dispensaries was advocated in a paper read before the society nearly 50 years ago. Other subjects discussed in the early years of this society were medical education and the necessity of turning hospitals to good account for purposes of teaching. In 1869 this society advocated a reform of the lunacy laws. I need not tell you that from the point of view of the medical profession the lunacy laws are not satisfactory and I believe that the public are no more contented than we are with the present condition of these laws. In 1870 the "one-portal" system was discussed and pressed upon the Lord President of the Council. Shortly afterwards the direct representation of the profession in the Medical Council and the appointment of a Public Prosecutor were the subjects of interesting debate. Amongst other questions of interest which underwent discussion may be mentioned the means of notifying to sanitary authorities the occurrence of infectious disease, the duty of corporate bodies to provide for the isolation of infectious disease, the working of the Factory Acts, and the position of ship surgeons.

I would now direct your attention to the desirability of having a Minister of Public Health. A governmental sanitary department will always have plenty of work in dealing with the problems arising from overcrowding in cities, such as the limitation of infectious diseases, the disposal of sewage, and many other questions which directly relate to the public health.

Many years ago in this society attention was directed to the benefit that the State would derive were the medical profession represented in the House of Peers. This is now an accomplished fact. All honour to the distinguished statesman who was privileged to advise the Crown to elevate Lord Lister, the first medical peer, to a seat in the House of Lords. Surely no one is more capable to give advice to a government on a variety of subjects than a highly educated and experienced medical man. Medicine is based upon many sciences, and our profession is the only one which possesses a wide knowledge of the conditions on which much of the comfort and happiness of life depends.

Much has been said of late years of the political powerlessness of the medical profession and while not altogether sympathising with this cry I see no reason why influential corporations like the Colleges of Physicians and Surgeons, with their numerous members practising all over the country, should not be represented in Parliament. We are not politically powerless. Although we do not care to take an active part in political agitations yet we greatly influence public opinion, and I am not sure whether our political power might not be diminished rather than increased by direct representation of the profession in Parliament. Action begets reaction and it is probable that a corporate representation would tell against us rather than in our favour. I have already advocated the appointment of a Minister of Public Health, but the powers intrusted to him ought to be exercised with great circumspection.

Much has been said regarding admission into the profession by the "one-portal" system and various views have been held by highly respectable authorities on this question. We have at present about 23 licensing bodies. The practical question is, Shall we abolish the existing powers of these institutions?—or should we content ourselves with enacting guarantees that they shall maintain the standard of their examinations at a sufficiently high level of attainments? In any scheme of State examination the standard of examination must be a minimum standard and the lowest prizes in the profession must fix it. The Government requires medical men for the navy and for the army and it would be impossible to make the standard of examinations so high as to exclude men who would be likely to accept such appointments. There are also parts of the country with widely scattered populations and no government will raise the standard of examinations so high that men will not be found to practise in those districts.

Opinions differ as to how far a government is justified in enforcing the practice of vaccination, in insisting upon absolute compulsory isolation in cases of infectious diseases, and in compelling corporations, property owners, and the public generally to observe wise sanitary laws. I do not believe that this country will ever turn its back upon the Vaccination Acts, but it will be well for the profession to be in readiness to advise the Government and the constituencies in this matter. In reference to the general isolation of the acute infective diseases, I believe it will be possible to obtain even more stringent regulations than we now possess as the people become more educated without the Government having to trench too violently upon the liberty of the subject. Sanitary regulations will be more carefully observed under the pressure of an educated public opinion without our being too ready to call out for coercive legislative enactments. Stringent laws, like every species of coercion, have a tendency to defeat themselves. A drastic sanitary law would at once call into being an anti-sanitation society, and it is only on condition that there was a strong educated and even uneducated public opinion in favour of the law that it would maintain its place upon the statute book.

Another subject which has received much public attention of late is over-pressure in schools. It is manifest that the pupils must possess a certain amount of intelligence before any teaching can be effective, and their faculties cannot be maintained and developed unless they are supplied with plenty of nourishing food and kept under healthy sanitary conditions. Underfed children cannot have well-developed faculties; therefore, they are not in the position to benefit fully by teaching, ho[illegible] instruction may be. In order tc [illegible] s been proposed to supply the [illegible] with a free midday meal. This scheme must meet with our approbation so far as the poor children themselves are concerned, but we ought to insist, in my opinion, that the project should be carried out by the payment of the parents aided only by benevolent contributions and without the interference or assistance of the Government. Without this restriction the responsibility of parents in rearing their offspring will be greatly diminished or annulled and a species of communism will be introduced. With regard to the method of teaching now in vogue I believe that there is too much cramming in our present system, that words are divorced from facts, and that names are taught without giving the child any knowledge of the things indicated by them. Kindergarten methods of instruction seem to me to offer immense advantages over the time-honoured system of teaching children from written characters and words.

University of Oxford: Degree Days.—Congregations will be held for the purpose of conferring degrees in Easter and Trinity terms on the following days—viz.: Thursday, May 19th; Thursday, June 16th; Thursday, June 23rd; and Saturday, July 9th.

EYESTRAIN AS A CAUSE OF HEADACHE AND OTHER NEUROSES.

By SIMEON SNELL, F.R.C.S. Edin.,
OPHTHALMIC SURGEON, SHEFFIELD ROYAL INFIRMARY; PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY COLLEGE, SHEFFIELD.

Of all painful affections probably headache causes the most distress and misery. The individual who never experiences headache is one much to be envied. Fortunately there are many able to say this. On the other hand, there are many afflicted with headache causing constant or recurring suffering and only too frequently so disabling the sufferer that life to him or her becomes a burden. Life is shorn of its beauties and not only are its pleasures curtailed but the actual daily occupation is interfered with. A consideration of some of the causes of this suffering and the measures which may be adopted for its relief is well worthy of our attention.

It has, of course, for some time been understood that certain instances of headache bear some relation to eye defects. But the far-reaching effects of eyestrain and the relief afforded by the proper correction of refraction errors are not by any means as widely recognised as they demand. It is a matter that, in my opinion, admits of no question. The evidence is continually before one. Again and again is the same story told, first of the suffering and then of the relief afforded by optical aid. In my last 800 refraction cases in private practice I find that 162 suffered from headaches. I do not include in this number those making the usual complaint of discomfort for which hypermetropes and early presbyopes so frequently solicit assistance. In the cases to which I refer the patients have at once volunteered that they suffered from severe headaches or have stated on inquiry that they did do so. In the great majority this constituted the cause for seeking advice. In most, also, in varying degrees, were associated some or all of the train of symptoms to be described later.

Perhaps no more important work has been accomplished in the whole range of medicine and surgery than that of placing anomalies of refraction on a firm scientific basis. This we owe in the greatest measure to Donders and it brought to him undying fame. It is well known, too, that astigmatism, which has such a close bearing on our subject, was discovered by Thomas Young, the physician as well as the physicist. Sir George Airy, the astronomer royal, described astigmatism in his own case. It was of the compound myopic variety and was monocular. Here it is of interest to note that Airy was the [illegible] described his own case in a pa[illegible] *Magazine* for 1865.[2] It may be [illegible] a proper correction of his refraction error, with the knowledge which we now possess, would in all probability have relieved him of his migraine, for he had both astigmatism and asymmetry in the refraction of the eyes, two very potent causes of headache as will be shown farther on. Airy's son, Dr. Hubert Airy, also published a very graphic description of migraine and the ocular symptoms in his own person[3] and it appears not unlikely from the account which he gives that he, too, would have been relieved, as has so often been the case in my experience in similar instances, if attention had been given to his eyes.[4] The interest that Young and Airy had in astigmatism was, however, physiological and not pathological. And even Donders lays stress always on the normal and abnormal astigmatism, the latter being astigmatism which interfered with the acuteness of vision. Our interest here is in the pathological significance of astigmatism and the subtle and powerful influences of eyestrain and not necessarily on its interference with visual acuteness. Frequently no complaint of vision is made and the error of refraction is only discovered after a careful and complete examination of the eyes.

[illegible] Medical Society on Feb. 24th, 1904.

[illegible] says, [illegible] I had [illegible] I am [illegible] oint is [illegible] ntary [illegible] 's. It [illegible] employment, close reading and [illegible] generally comes on while the eyes are engaged with toilsome reading."

As far as I am aware the first to recognise clearly the close connexion existing between headaches and other neuroses with eyestrain was the distinguished physician and writer, Weir-Mitchell of Philadelphia. In a series of articles he urged the importance of a proper understanding of this relation. The views which he set forth are so well expressed and have such a practical bearing that they may still be read with profit[5] by those interested in the subject. He recognised that the distant symptoms may be the indication of eyestrain when no complaint is made of any defect of sight and this is a point of the greatest practical moment. He cites several cases from his experience and says of them "that the cases just told seem to me enough to prove that the eyes may long rest unsuspected as the cause." I make here the following quotations:—

> My consultations have plainly enough taught me that hardly any men in the general profession are fully alive to the need of interrogating the eye for answers to some of the hard questions which are put to us by certain head symptoms, since many of the patients treated successfully by the correction of optical defects never so much as suspected that their eyes were imperfect. What I desire therefore to make clear to the profession at large is:—1. That there are many headaches which are due indirectly to disorders of the refractive or accommodative apparatus of the eye. 2. That in these instances the brain symptom is often the most prominent and sometimes the sole prominent symptom of the eye troubles so that, while there may be no pain or sense of fatigue in the eye, the strain with which it is used may be interpreted solely by occipital or frontal headache. 3. That the long continuance of eye troubles may be the unsuspected source of insomnia, vertigo, nausea, and general failure of health. 4. That in many cases the eye trouble becomes suddenly mischievous owing to some failure of the general health or to increased sensitiveness of brain from moral or mental causes.

Lauder Brunton some years ago[6] also very forcibly pointed out that the cause in many cases of headache must be sought in some irritation of the sensory nerves. It was to be found in the teeth, eye, throat, and nose. He makes references to the teeth as starting irrritation of sensory nerves and does so with excellent illustrations. He then says:—

> Perhaps a still more frequent source of headache than even decayed teeth are abnormal conditions of the eyes. The headache which comes on after working with the microscope or after straining the eyes in a picture gallery is only too well known. It is usually frontal, often extending over the whole breadth of the forehead but sometimes limited to the forehead above one orbit. It would be going too far to say that frontal headache is always due to an abnormal condition of the eyes, but I believe it is so much *more frequently than one would* at all suspect. . .. But frontal headache is not the only one which may arise from abnormal conditions of the eyes, for megrim or sick headache is very frequently associated with, and probably dependent on, inequality of the eyes, either in the way of astigmatism, myopia, or hypermetropia.

Since this time others in this country have written on the subject, notably the late Mr. H. B. Hewetson of Leeds. But in America it has received much more careful notice than in this country Recently Dr. George M. Gould of Philadelphia in able articles in THE LANCET[7] and the *British Medical Journal*[8] has called attention to the effects resulting from eyestrain and the treatment which they demand.

Before going on to the consideration of the class of cases with which this paper is chiefly concerned a few words may be said about migraine, for many instances of this disorder in which the classical symptoms are present will be relieved by giving attention to ocular errors. Two medical friends who have been closely associated with me have experienced an almost entire absence of the disorder since their astigmatism was corrected. One of these had several attacks of typical migraine. The last attack, which brought him *to me for* examination, he thus describes:—

> I went to the ward to do a sugar determination. I then found I could see only the right half of the meniscus at the top of the fluid. In ten minutes (I noted the time) a black star appeared in the centre of the field. It lasted about 30 seconds and then enlarged; the vision in the cer[illegible] [illegible] id towards the left side of the field there app[illegible] [illegible] ectrum. It lasted like this for 20 minutes, [illegible] moving away from the centre. For an hour f[illegible] headache on the right side. This was intensified by lowering the head to use the stethoscope, coughing, and contracting the scalp muscles. There was no tenderness of scalp. For several hours afterwards there was a dull pain in the right occipital region on coughing or lowering the head.

In May, 1902, he came to me and I found myopic astigmatism (– 1 D. with 0·25 D. cyl.) in the left and myopia (– 1·5 D.) in the right eye. He wore the correcting glasses constantly and had no further attack of migraine until a year later. Then an attack followed his leaving off the glasses for reading in the evening. He again took to the use of the glasses constantly and no further attack has occurred.

The other case was the following. A youth, aged 14 years, began to have typical attacks of migraine which were always precipitated by reading. At the age of 22 years he was ordered convex spherical lenses which gave practically no relief. At the age of 25 years I carefully estimated his refraction under a mydriatic. In the right with + 1·5 D. sph. and + 0·5 D. cyl. vert. V. = $\frac{6}{6}$; in the left with + 1 25 D. sph. and + 0·5 D. cyl. vert. V. = $\frac{6}{6}$. Cylindrical in combination with spherical lenses were prescribed and gave the greatest relief. He still continues to have migraine but the attacks are transient and at much longer intervals. *He can now read and write for hours at a time* without fear of precipitating an attack. The correction of the astigmatism has been most marked in relieving the nausea and dyspepsia.

The headaches, however, which we have now to consider belong to a different category. It will be well, therefore, to specify in some detail the situation and character of the headache met with, together with other associated symptoms. The pain may be frontal, across the forehead, or just above the eyes, limited to the supra-orbital region or reaching to the hair. This frontal situation is perhaps the most common. It may also be in the temples. It may be between the eyes and at the root of the nose (fronto-nasal). The pain is frequently paroxysmal and called neuralgic or it may be a more dull continuous pain. Usually it is bilateral but it may affect chiefly one side, one eye, one temple, or one side of the forehead. When this is the case it is often described as neuralgia, especially when affecting the eye. Unilateral headache is often associated with astigmatism on that particular side, whilst the other eye may be normal in refraction or have ametropia of less consequence. Pain may be at the vertex and this is a frequent seat. It may be a dull continuous pain or it may be of a dragging character. One lady described it as if an "iron claw was gripping her head." The occiput is another situation where pain is localised. It may extend down the nape of the neck to the spine. A lady referred to the pain as if a large crab had seized her by the nape of the neck, whilst another said the feeling was as if thousands of strings were in the back of the neck and as if someone was pulling them. In some the pain is confined to the neighbourhood of the eyes, forehead, or temple, whilst in others it may be associated also with vertical or occipital pain. It may, moreover, be continuous, lasting for long periods, or it may be intermittent. Some speak of never passing a day without suffering whilst others may have a headache daily or be free for portions of the day; others suffer once or twice a week and others again only at longer intervals. The pain is sometimes relieved by pressure over the most painful part. Giddiness is a frequent complaint in these cases, causing often such a tendency to fall that it necessitates keeping very quiet and is a reason for seeking advice. Associated with headache not infrequently is a feeling of misery or apathy, a dulling of interest in things. One gentleman mentioned his "inability to think," but cylinders of + 0·25 D. aided him greatly in this respect. Irritability of temper, too, is mentioned. Insomnia is a frequent complaint and it is interesting to notice how speedily natural sleep returns after relief has been afforded by correcting glasses. Sleep is spoken of as not restful, as being often disturbed by dreams and nightmare. The general effect on the nervous system is such that a "nervous breakdown" is spoken of. A lady wrote to me respecting her cook who, she feared, was getting her brain affected, and yet this, together with constant headache, yielded to attention to the eyes.

Blinking and winking are, it is well known, not infrequently met with, especially in children with eyestrain, and these symptoms disappear when the ocular defects are corrected. Less frequent are choreiform-like movements affecting not only the eyelids but the muscles of the face and even the occipito-frontalis. A young patient, suffering in this manner, recently under my care, yielded at once when his hypermetropia and astigmatism (R. + 2 D., L. + 1·5 D. with + 1 D. cyl. vert.) were corrected, whereas several months of medical treatment had failed to benefit. Vomiting and nausea are common symptoms. The former may be severe and lasting and attended with much retching. It may render a patient prostrate and necessitate confinement to bed. More frequently nausea is complained of, a sickly feeling after using the eyes. Indigestion is often mentioned or ascertained on inquiry. These patients frequently present an anxious, worn look and the difference, when relief has been afforded to the distressing symytoms, is evidenced often very clearly in the facial expression. The symptoms differ often considerably in each patient.

---

than a hund[illegible]ilisation."

It has been mentioned that nausea and vomiting are met with not infrequently in these cases. This is of considerable interest, for it is well known that they are prominent and well-recognised symptoms of some eye diseases. An attack of acute glaucoma is ushered in with severe pain in the eye and the head and attended with violent vomiting. The bilious attack is such a prominent symptom that it masks the eye condition. *It therefore receives attention; the eye is unheeded* and treatment of the glaucoma is frequently deferred until sight is lost. If the reverse plan had been adopted and an iridectomy performed or even eserine instilled a clearing up of the general symptoms would have followed and the eye would have recovered its sight. Vomiting and the so-called "bilious attack" would have ceased on the relief to the increased tension of the globe which the measures mentioned would have brought about. Another example may be given. Increased tension of the eyeball is indicated in injuries to the crystalline lens or when a needling operation for cataract has been performed, not merely by pain in the eye but often by vomiting. Here, again, removal of the swollen lens is followed by immediate relief to the stomach symptoms. The disturbance of the pneumogastric nerve by these conditions is well recognised. It is not difficult to understand that the attempts of the ciliary muscle to overcome defects should similarly influence the pneumogastric nerve. It must be borne in mind that the ciliary muscle is perhaps the only muscle the action of which is continuous. Sleep is the only time for recuperation.

The remedy for the condition met with in these cases is attention to the eyes. Over and over again in my experience, relief has been afforded by the correction of anomalies of refrac [illegible] expresses regret at not having [illegible] wasting time upon other m[illegible]tment is necessary. A faulty state of the eyes is ascertained; it is corrected, the proper glasses are worn, and relief follows, whilst the other conditions of life have been unaltered. This is proof sufficient. It has been well said:—

> If use of the eyes produces any of these results it is almost surely the cause; if disuse of the eyes relieves, it is doubly sure, if without the disuse of the eyes wearing of proper glasses does the same, the demonstration is beyond question (Gould).

In many cases which come before one, however, the symptoms have already existed for a long period and immediate relief from the wearing of the correcting glasses cannot be expected any more than that a chronic disease should at once yield to any treatment which may be adopted for it. If anyone wishes to learn what the astigmatic eye has through the ciliary muscle to overcome he can do so by placing + or − cylinders before his eyes. Let him wear these glasses and they will produce the symptoms of ametropia. To illustrate, though imperfectly, the indistinctness of type which a low degree of astigmatism occasions if uncorrected by the action of the ciliary muscle I have had a series of photographs taken of a portion of a *Times* leader. First, the leader was photographed in the usual way and appeared sharp and clear. Then, under precisely the same conditions, the same was again photographed but close to the lens of the camera a cylindrical glass was placed. In this way a series of photographs was taken with + 0 25 D. cyl.; + 0·5 D. cyl.; and + 0·75 D. cyl. respectively before the lens of the camera. A second series with similar minus cylinders was taken. In each case the cylinder was so placed to occasion the effects of an astigmatism "according to rule." The eye naturally strives after a clear and sharp image and as this can only be accomplished by the action of the ciliary muscle the photographs[9] will be understood as illustrating the strain which the astigmatic eye must undergo to accomplish this result.

The following cases may be given as illustrations of those we have under consideration. The first is that of a lady who had suffered for a considerable time. She is the wife of a medical practitioner at a seaport on the east coast and he has very kindly written the following account for me.

> The patient, aged 32 years, had studied music until she was 21 years of age, spending five years in hard study in Germany. There were no eye symptoms then except headache occasionally. When working for a concert five years ago she began to have attacks of giddiness and occipital headache. These ceased after the concert but returned with increased force 12 months later when she was again working up for a concert. On this occasion she had one or two attacks of sickness. Improvement again took place. A few months afterwards she had some lessons in London and practised hard, ultimately having a complete breakdown from headache, giddiness, and nervous attacks. Then she gave up playing but for a long time her general health was poor. She was thin, did not sleep well and was very nervous. She developed a cough and consulted a well known physician nearly two years ago. He found no organic disease but ordered her to feed up. Her general health improved somewhat and then she began to have the typical attacl [illegible] fortnl [illegible] every [illegible] been [illegible] fall a[illegible] and lasted for several hours with severe straining and retching. After an attack she was prostrate and [illegible] Occipital headache was frequent and [illegible] seized her by the nape of the neck. [illegible] come on with startling rapidity, almos[illegible] one occasion I remember she was sitti[illegible] cheerful. Suddenly she became q[illegible] off the chair. She was pale and f[illegible] to a couch. In a quarter of an hour she was vomiting. The worst attack she ever had came on during the night when in bed. The slightest attempt to lift her head from the pillow brought on frightful nausea and giddiness. After consulting you and wearing the glasses you prescribed she had several attacks during the first four weeks but they did not culminate in vomiting, and she has not had an attack of vomiting since (excepting once she had a bilious attack from eating some indigestible food; on this occasion there was no giddiness and she was "comfortably sick", in an hour or two she was well). The attacks of headache and giddiness [illegible] and she is now free from any trouble of this [illegible] thousands of strings were in the back of the neck and as if someone were pulling at them. The giddiness always commenced in the occipital region."

The refraction ascertained after using a mydriatic was as follows: R. − 0·75 D. = $\frac{6}{6}$, L. −1 D. = $\frac{6}{6}$, axes vert.

The next is a more acute case and is one of considerable interest apart from the question of his headaches, for five years ago, when studying at the Sheffield Technical College the patient was struck in the right eye by a splinter of steel which penetrated the globe and became imbedded in the retina near the optic disc. I was successful in removing this particle of steel with the electro-magnet; he recovered perfect sight which, as the record now shows, has been permanent. The patient, aged 27 years, is an engineer and lecturer on electrical engineering at a technical school in a great midland city. He has always been a hard worker and the following is an account of his work during the last few years.

> From Septem[illegible]tured in the evenings Con[illegible] August to October, 1901, [illegible] and a half hours a day). [illegible]rs' research work involving [illegible]t on m.m. scale; 50 readin[illegible]imes a day for several wee[illegible]red paper, &c. Nearly wh[illegible]re), most of work being do[illegible]tmas, 1903, reading and lecturing. There was no serious difficulty experienced with eyes during the whole of this time except that there was sensitiveness to strong light, which was considerable on waking and when the eyes were tired with rea[illegible] to a colder atmosphere and [illegible] just before Christmas, 190[illegible] careful dieting. He had a [illegible] during which time he did [illegible] had no food but got up for an hour. On the 9th he was able to eat a

---

[9] Lantern slides were shown to illustrate this.

small piece of fish. On the 10th he came downstairs at noon and had light diet. His medical adviser prescribed a tonic. He had to be assisted upstairs on account of dizziness. On the 11th, 12th, and 13th he came down about noon daily. On the 14th diet about normal; went out of doors for the first time but was dizzy, otherwise felt well. On the 15th and 16th the dizziness slowly decreased. On the 16th he came to Sheffield and consulted me. On the 17th dizziness was still less. The eyes were absolutely at rest from Jan. 7th to 17th. He has not complained so much of headache. The feeling in his head was more of general muzziness, with occasionally acute pain in the eyes and forehead. The dizziness, he mentions, is that he feels about to fall and everything around seems to be swimming.

The refraction in this case was R $+ 0·75$ D. cyl. $60° = \frac{6}{6}$; L. $+ 0\ 75$ D. sph. $= \frac{6}{5}$. Subsequently he gave this report :—

> I am glad to say that I am now in normal condition having worn the glasses continuously as you advised. The dizziness gradually disappeared and during the last few days I have felt quite free from any indications of weakness, although I am doing a considerable amount of extra work owing to the illness of one of the lecturers here. Am doing a third of his work (lectures, &c) in addition to my own. Once or twice I have tried the effect of not using the glasses for an hour or two but this gave rise to headache and acute pain at times in the right eye, not prolonged. Also the dizziness began to return.

It has already been mentioned that of the last 800 refraction cases in my private practice 162 sought advice in consequence of headache more or less conforming to the types which have been described—that is to say, about 1 in every 5. Dr. A E. Barnes, a late clinical assistant of mine, has very kindly collected from my private case books 318 consecutive cases and has prepared for me the following analysis.

in age was a man, aged 52 years, with simple hypermetropic astigmatism, + 0·75 D. cyl. in each eye according to rule (approximately). In males the ages at which eyestrain headaches are most prevalent correspond to three periods of life—i.e., puberty, from ten to 15 years; age of greatest stress, from 20 to 25 years; age when accommodation is failing, from 45 to 50 years. Myopic astigmatism is again different to the other errors, for five out of 11 cases were over 35 years of age, corresponding to the last period. In females the prevalence belongs to the period of sexual activity, for they begin to be common at 15 years, reach a maximum at from 25 to 30 years, and finally disappear at 50 years.

As to the relative frequency of the different kinds of ametropia it was found that the kind of error most associated with headache was hypermetropic astigmatism. Pure hypermetropia was nearly as common, myopic astigmatism much less common, mixed astigmatism still less common, whilst myopia was only present in four cases, and in three of these there was also anisometropia. The analysis of 300 cases gave the following results: hypermetropic astigmatism, 49·3 per cent.; hypermetropia, 34 3 per cent.; myopic astigmatism, 11·3 per cent.; mixed astigmatism, 3·6 per cent.; and myopia (three of which were unequal in the two eyes), *1·3 per cent.*

Of particular interest in this analysis of cases of headache and errors of refraction associated with them is the large number of cases in which the degree of astigmatism is a low one and the cylinder prescribed correspondingly weak. There is in some quarters a failure to recognise the importance of estimating these low degrees of astigmatism and the value derived from the use of weak cylinders. A careful study of the subject, however, will easily demonstrate that the low degrees of astigmatism play a very important rôle in the causation of the neuroses we have under consideration. They will be found in patients complaining little, if at all, of their sight and can only be detected and the exact axis ascertained after a careful examination when the eye is under the action of a mydriatic. I refer especially to astigmatism of 0·25 D. and 0·5 D. Included in my series were 144 cases of hypermetropic astigmatism, simple and compound. I find that + 0·25 D. cyl. was prescribed in 18 cases of simple and five of compound hypermetropic astigmatism, or 23 cases altogether; + 0·5 D. cyl. was prescribed in 38 and 9 respectively, or 47 cases; and + 0·75 D. cyl. was prescribed in 22 and eight respectively, or 30 cases, thus making a total number of 100 out of the 144 cases in which cylinders of + 0 75 D and under were prescribed. The benefit of these weak + cylinders was undoubted. There were also 34 cases of myopic astigmatism, simple and compound. For these cylinders of − 0·75 D. and lower were ordered in 20 cases—viz., − 0·25 D. cyl. in three simple and one compound, or in four cases; − 0·5 D. cyl. in four simple and two compound, or in six cases; and − 0·75 D. cyl. in nine simple and one compound, or ten cases. The percentage for these weak cylinders works out as 66·8 per cent. for hypermetropic and 58·8 per cent. for *myopic* astigmatism. The following is a case illustrative of the

TABLE SHOWING AGE, SEX, AND AMETROPIA IN A SERIES OF HEADACHE CASES.

Age.	Sex.		Total.	Hypermetropia.			Hypermetropic astigmatism (simple and compound).			Myopia.			Myopic astigmatism (simple and compound).			Mixed astigmatism.		
	M.	F.		M.	F.	Total.	M.	F.	Total.	M.	F.	Total.	M.	F.	Total.	M.	F.	Total.

Over 55	—	1	1	—	—	—	—	—	—	—	—	—	—	1	1	—	—	—

The age was not mentioned in 28 cases—4 of hypermetropia, 23 of hypermetropic astigmatism, and one of myopic astigmatism. The figures in brackets denote the number in which there was anisometropia.

Sex.—Females predominated largely. This was especially the case in hypermetropia and hypermetropic astigmatism. In myopic astigmatism this preponderance was much less. The following figures illustrate this point. Of the total cases 84 per cent. were females; of cases of hypermetropia 89 4 per cent. were females; of cases of hypermetropic astigmatism, 89·4 per cent. were females; of cases of myopic astigmatism, 64 per cent. were females. The preponderance of females is hardly to be wondered at. Women are more subject to neurotic conditions than men. The mental or nervous stress more rapidly affects them. Their nervous system is less stable. Women have more constant close eye work than men and their lives are passed more indoors than men. They have more leisure for reading and spend much of their time in sewing and fancy work—the latter and "bazaar work" often being responsible for a breakdown and a visit to the ophthalmologist. *It is the eyeworkers*, whether male or female, that are prone to headaches and the train of other neuroses which have been mentioned. These have been illustrated in the cases which have been related.

Age.—The youngest case was that of a boy, aged six and a half years. His refraction was R. + 1·5 D.; L. − 0·75 D., axis vert. Some time previously he had undergone tenotomy for convergent squint. There were two girls, aged seven years, one had H. + 1·5 D. and the other H. + 1 D. in each eye. The oldest was a woman, aged 60 years, with one available eye. L. − 1 D. with cyl. − 0·75 D., vert. approx.[10] The next value of weak cylindrical lenses. It has been related before and is epitomised here.

---

[10] "Approximately" vertical or horizontal is used as indicating that the axis approaches one or other of these meridians. This suffices for our purposes here, but in testing, the axis must be determined exactly if relief is to be afforded.

In consequence of long continued and severe headaches a gentleman, a missionary in the East, consulted me in October, 1901. The headaches had commenced about February, 1899, after considerable stress of work. They began on the left side, to which they were chiefly confined, sometimes beginning about the eye and at other times about the teeth. At first there was a sort of hot feeling which, after a time, gave place to a more acute pain, apparently like neuralgia. When pain was absent there was a numb feeling reaching from the left side and top of the head to the occipital region. The feeling was as if one side of the head was boiling hot or in flames and he lost all energy. His sight was tested by a medical man and declared to be *above normal*, and the complaint was designated "hemicrania," "cause undiscovered" being put in the certificate. It was suggested at this time that his teeth might be responsible and he consequently had two extracted from the upper jaw. As a result of this examination he was invalided to another part of the country for six months but he was able to do some work. The change and comparative rest were beneficial and he was able to resume regular work in the autumn of 1899, continuing it until the beginning of 1901, when the headaches recurred. He was treated without avail by another medical man who regarded the headaches as rheumatic. In February, 1901, he left for England, arriving in this country in the middle of April. He was then brought before the medical board who ordered six months' rest, at the expiration of which time he was re-examined. The headaches still remained at that time but were somewhat modified in severity. The principal medical officer could not diagnose the cause and advised him to see an ophthalmic surgeon. He therefore came to me. At his visit I found that, though suffering from headache, it was not so bad as previously. The numb feeling was constant and there were exacerbations of more acute pain. He was of opinion that the headaches were made worse by exertion, but as he was unable to use his eyes with comfort he believed they had a good deal to do with his suffering. Vision in each eye was *normal* ($\frac{6}{6}$) *and glasses rendered it worse.* After being under the action of homatropine and cocaine in each eye V. = $\frac{6}{6}$, or with + 0·5 D. cyl., axis horizontal, $\frac{6}{5}$ The muscle balance appeared to be normal. These cylinders were ordered and a week later he reported himself as improved and better than he had been for a very long time. He also added that the numb feeling in the head disappeared when wearing the glasses but returned on leaving them off. He mentioned an interesting fact that two days previously after a bicycle ride the pain in the head returned and he wished to know if cycling would be injurious. He had cycled a good deal when in the East and thought the pain had been aggravated thereby. I explained the way in which it might be so and was informed that he had been in the habit of leaning forward, and consequently, on looking straight in front of him, he would have to use and strain the elevator muscles and discomfort would be caused in the same way that "academy" or "sightseers'" headache is occasioned by looking at pictures hung above the line. At a later call he stated that he had received considerable relief and was anxious to return to work and desired my permission for him to accept a curacy in the south of England. He was able to read with much greater comfort than formerly. He also said that he was satisfied as to the cause of the strain to the eyes when cycling as he had put himself in the position I had explained and he found the eyes to tire very soon. On Nov. 22nd I again saw the patient who expressed himself as better and more fit for work than he had been since he first commenced his labours in the East. He was able to read with comfort for long periods and felt confident of being able to fulfil his clerical duties which he was to enter upon the next day. Later he obtained permission to marry and to return to his work in the East.

Anisometropia, or an inequality in the refraction of the two eyes, is another feature to be noticed and it is important. One eye may be myopic and the other hypermetropic, or both may be myopic or hypermetropic, but the degree may be higher in one of the eyes or the degree of astigmatism may be unequal in each eye. Moreover, one eye may be normal and the other may have some form of ametropia A consideration of my cases shows that inequality of the two eyes was present in nearly half (45·6 per cent.) It was most frequent in mixed astigmatism (81 per cent.). Myopia came next with 75 per cent. and myopic astigmatism with 74 per cent. In hypermetropic astigmatism it was present in 55 per cent.; in hypermetropia only in 21 per cent. In compound astigmatism, both hypermetropic and myopic, it was more common than in the simple varieties. In hypermetropic astigmatism the axis according to "rule" should be horizontal and in myopic astigmatism it should be vertical. There is but little evidence from my cases to show that astigmatism against the rule is especially potent in causing headaches. In hypermetropic astigmatism there were only nine cases against, or approximately against, the rule (i.e., about 6 per cent.). There were also 14 cases in which there was astigmatism against the rule combined with inequality of degree, but as anisometropia is such a powerful factor in the production of headache these cases can hardly be used to show that departure from the rule is also a factor. In myopic astigmatism there were no symmetrical cases against the rule where there was not also inequality of degree, but there were nine cases in which there was also this inequality of degree. If we do not take account of those cases in which one eye only was astigmatic we find that there were 13 cases of hypermetropic astigmatism in which the axes were not symmetrical. This is not quite 10 per cent. In myopi astigmatism there were nine cases, or nearly 25 per cent.

The correction of these conditions without glasses could only be brought about by an effort of accommodation differing in the two eyes and this, it is thought, the eyes are hardly capable of doing to any great extent. Where the difference is considerable the inconvenience is not always great and persons often only become aware of the fact that they do not see equally well with each eye when the tests for vision are applied. In a case like that of Mrs. ——[11] in which there were myopia and amblyopia (V. = − 10 D. with − 1·5 D. cyl. $\frac{6}{24}$) *in the right and hypermetropic astigmatism* (+ 0·75 D. cyl. = $\frac{6}{6}$) in the left, the chief factor in giving relief to her headaches probably was the correction of the astigmatism in the left, though a minus spherical glass with a cylinder was at the time prescribed for the right. In other cases the effort to accommodate with each eye will be made, especially in low degrees of asymmetry, and this endeavour is often attended with considerable discomfort and headache, &c., and is an important factor in occasioning the distressing conditions which we are discussing.

If relief is to be afforded in these cases it is of the utmost importance that the refraction should be carefully and thoroughly worked out. To accomplish this the use of a mydriatic is essential. It has been pointed out that many of the greatest sufferers make no complaint of their eyesight and unless therefore the accommodation is paralysed and the exact refraction ascertained relief will not be afforded. For this purpose homatropine, especially in combination with cocaine, is usually sufficient[12] I generally employ it made up in gelatin discs. If these are used two or three times at intervals of ten or 15 minutes a patient is ready for examination at the lapse of from one and a quarter to one and a half hours. The next day the effect has passed off sufficiently for the patient to be able to read with his correcting glasses. A mydriatic will reveal a latent hypermetropia of one, two, or even three dioptres not infrequently in those aged 38 years, 40 years, or even more, and the low degrees of astigmatism will not be discovered without it. Homatropine used in the way already mentioned usually suffices, but its employment has in some cases to be repeated daily.

Retinoscopy is the one objective method that is of real value. Its discovery has rendered immense service to refraction work. For young children it must often be relied on for ascertaining the degree of the error and it may often be necessary to prescribe spectacles from its findings. For all others, however, the final examination must be made with the trial glasses and test type cards. No objective method can be permitted to dispense with these. Ascertain carefully the best correcting glasses and be very exact as to the axes of the cylinders. Attention to these matters is essential if our treatment is to be successful.

It must not be forgotten that whilst an error in the refraction is responsible in the main for the headaches and other conditions in these cases there nevertheless is in some added thereto a faulty condition of the muscle balance of the eyes. This, though secondary, is still an important factor and the latent deviation must be carefully ascertained by the use of Maddox's rod and tangent scale. The close relation between the external ocular muscles and the accommodation is such that it suffices not infrequently, after careful testing, to relieve the ciliary strain by the appropriate glasses. The muscle balance becomes rectified or of less account. This is not, however, true of all cases and the adaptation of prisms must then be combined with such correction as the refraction error requires. Exophoria, or latent divergence, is the condition most frequently met with. It occurs much more frequently than the opposite condition or esophoria. It is often present in myopia and in the comparatively few instances that headache is associated with myopia, apart from astigmatism and anisometropia, it may be regarded as the cause. Tenotomy of the external recti is sometimes indicated and is of service. The following case illustrates well the benefit of taking into account the muscle balance as well as correcting the ametropia.

---

[11] "Before wearing glasses I used to suffer constantly from headaches [illegible] pains in [illegible]

Twelve months ago a medical student came to me from Scotland. His headaches were so intense and so constant that study was almost impossible; his examination had been postponed in consequence and he was considering relinquishing his medical career, at all events for a time. He had previously consulted two ophthalmic surgeons; each had prescribed glasses but neither had ascertained the refraction as revealed by a mydriatic. He had accordingly received no benefit. Homatropine and cocaine were used by me for two days. The refraction then was R. + 0·75 D. sph. with + 0·25 D. cyl., axis vert.; L. sph. + 0·75 D. These were ordered for general use and later for the exophoria which was present prisms 1°, base in, for each eye were prescribed. These gave complete relief; he soon wrote that he was able to do a normal amount of work and that he was preparing with confidence for his final examination. This he was successful in passing. The following is an extract from one of his letters:—

> The prisms seem to have worked almost a miracle. I do not, of course, wish to depreciate the other factors, yet the most marked difference occurred after the prisms were worn. I am now able to read the whole day and about two or three hours in the night, a pleasure which has been denied me for more than three and a half years. The terrible photophobia, conjunctivitis, constant headaches, and utter mental depression have all disappeared. I feel quite a different person. While not expecting to have the eyes I had five years ago it is quite an unspeakable felicity to be able to read as much as I do now and cover the work of the examination which lies before me. It is impossible to realise that for periods of three months at a time I was hardly ever free from severe headaches, that I was unable to look at a book for six weeks at a time, and that this state of sublimated mental and physical torture lasted for some years.

At the close of last year he wrote saying he had ceased for a time to use the prisms, wearing the correcting glasses alone, but as he felt the old symptoms returning he was taking to the prisms and again finding the same relief.

Vertical deviations are less frequent than lateral, but in my experience they have been associated with severe headache. One case was that of a nurse who was frequently laid up and who had been obliged for a time to give up her occupation. I found in the right eye mixed astigmatism (+ 0·75 D. vert., − 0 25 D. horizontal) and in the left simple hypermetropic astigmatism (0 75 D. vert.). Glasses were ordered combined with prisms correcting the vertical deviation. Very considerable relief was experienced.

A word now as to "academy" or "sightseers'" headache or, as it is called in America, "theatre headache." There is no doubt that astigmatism or some other form of ametropia is a factor in its production. But a proper correction of such defects will not always prevent this kind of headache and I feel certain that there are other important influencing conditions.[13] A lady mentioned that she suffered so much from headache after attending a play that she ceased to think a visit to the theatre was worth the after-suffering. It was also ascertained that she visited the pit and it was the effect of looking up at the stage that she found distressing in its after-effects. When sitting in the dress circle and looking on to, or down to, the stage she experienced less ill results. My investigations into the conditions causing the nystagmus, or rolling of the eyes, met with in miners showed that it was due to the weariness induced in the elevator muscles of the eyeball by the constrained position in which the miner had for long periods together to cast his eyes when engaged in working the coal. My observations in compositors, plate-layers, and many other occupations, indicated, moreover, that prolonged use of the elevators tended in them also to produce nystagmus but that in many instances only discomfort and aching of eyes were complained of. I believe, also, the cause of academy headache is in many cases to be found in this throwing the gaze above the horizontal line, especially without a corresponding uplifting of the head. Watch the visitors to a picture gallery and it will be observed how often this turning upwards of the eyes is required, especially when the paintings are hung above the line, and careful observation will show that many of the same visitors will compensate for this movement above the horizontal by a backward motion of the head. Anyone may try this for himself and observe the tiring effects occasioned by looking at pictures more or less skied and then notice the difference of looking at the same objects but relieving the elevators by at the same time throwing the head backwards. The collier with nystagmus learns to steady his eyes by turning them downwards. And it will have been noticed that the lady before referred to had herself observed the difference in looking up at the stage from the pit and looking down from the dress circle. Cyclists suffer from this kind of headache, particularly those who lean on the handle-bars with the head lowered, when if they look forward the gaze is necessarily directed above the horizontal line. I have already related a case in which a return of the headache resulted from a rather long cycle ride. As already stated, on questioning the patient it was found that he was in the habit of looking in the direction I have suggested as occasioning the weariness of the elevators and consequent headache. The accuracy of this observation he was able to endorse from tests which he made himself. I mention this particularly because I think that it is an explanation of the headache or eyeache sometimes complained of by cyclists and the cause once recognised admits of easy remedy.

We may summarise what has been written under the following conclusions: 1. That eyestrain is the cause of a large proportion of headaches, often of a very aggravated character. 2. That various other neuroses are met with in association with headache and among these may be mentioned the following: mental depression, nausea, indigestion, vomiting, insomnia, giddiness, choreiform movements of the eyelids and face, &c. 3. That relief is afforded to these conditions by correcting the error of refraction which can be ascertained only after careful examination. 4. That for such examination a mydriatic is absolutely essential. 5. That frequently no complaint is made of defect of vision. 6. That the ametropia is frequently of low degree, 61·2 per cent. of my cases needing 0 75 D. cyl. and weaker. 7. That a cylinder of 0·25 D. is of great value. 8. That anisometropia is frequently present and requires proper adjustment. 9. That in a certain number of cases the muscle balance is faulty and necessitates the prescribing of prisms.

Sheffield.

THE

TREATMENT OF MUCO-MEMBRANOUS COLITIS.

BY DR. DE LANGENHAGEN,
CONSULTING PHYSICIAN AT PLOMBIÈRES.

THE study of muco-membranous colitis has been largely extended of late years owing to the publication of numerous works, principally in France (Potain, Dieulafoy, Gaston Lyon, A. Mathieu, de Langenhagen, Froussard, and others) To-day the description of this disease to be really clear and complete needs a development that far exceeds the space available in a medical journal. Hence I am obliged to limit myself in this paper to presenting to the English medical profession the aspect of the question exclusively in its relation to the *treatment* of the disease, leaving to the authors mentioned above the history, symptomatology, complications, etiology, and pathogeny of the disease. It is, however, necessary that before I begin I should present a succinct clinical picture and give in a few short paragraphs my personal ideas which may be found in a more complete form in the little book that I published in London last year.[1] Muco-membranous colitis is a chronic catarrhal inflammation of the mucous membrane of the large bowel. It is a constitutional and diathetic disease, neither parasitic nor contagious. The soil in which the disease takes root and spreads is a constitution both gouty and neurotic—i.e., the neuro-arthritic constitution that is so common to-day and so largely increased and developed by the conditions of modern life, the repetition of hygienic errors, heredity, overstrain, and the heated atmospheres of large cities. To say to what extent respectively these two arthritic and neurotic elements are associated with the genesis of the disease would be difficult, as it varies according to each individual case. With certain persons it is the arthritic element which predominates and the physician may generally observe that in this case the colitis is less severe and more easily curable. In other cases there is, on the contrary, a predominance of the neurotic element and the physician has to deal with veritable neurotics who have lost their nervous equilibrium and whose case has been probably one of a primitive nervous trouble of the whole sympathetic system of which the catarrh and intestinal atony form merely a portion of the factors. From a symptomatic point of view muco-membranous colitis is essentially characterised by very pronounced intestinal atony and by a more or less abundant secretion of a mucoid or membranous matter. If the mucus is expelled as it forms it appears in the form of glairy threads analogous to the white or yellow of an egg and occasionally tinged with blood; if, on the contrary, it remains in the folds of the intestine it dries up and shows itself as a membraniform production of varying aspects (ribbons resembling segments of tænia, vermicelli, macaroni, and the like). The intestinal atony manifests itself by obstinate constipation, generally anterior to the signs of catarrh, and it is precisely the prolonged constipation which in the end brings about the mechanical irritation of the mucous membrane, its superficial inflammation, and the hyper-secretion of its glands. Nevertheless, alternations of constipation with diarrhœa are often found and exceptionally permanent diarrhœa.

To these two fundamental elements of the disease may be added a third which is but seldom absent—and that is pain. I have classified this as follows: either habitual pain with the sensation of a weight and a dull discomfort, generally seated in the iliac fossa and making itself most generally felt four or five hours after meals, or pain in paroxysms, very violent attacks which last some days and oblige the patient to take to bed and which are often taken for an attack of hepatic colic or of intestinal stoppage. The pains correspond to a state of spasm of the large bowel, more or less violent and more or less generalised. Objectively we regularly see in patients suffering from colitis a flabbiness and depressibility of the abdominal wall and a remarkable state of atony and laxity of certain segments of the large bowel, particularly of the cæcum, which feels like a more or less swollen sausage. On the other hand, the sigmoid flexure is generally contracted and forms a sort of string. Very often there is a general bearing down of the bowel or enteroptosis. Functional troubles of the stomach and the liver (flatulence, dilatation, hypochlorhydria or hyperchlorhydria, oligocholia or polycholia) accompany the intestinal symptoms and sometimes obscure them to such a degree that medical men not familiar with colitis see in their patients simple dyspeptics. Intestinal lithiasis is a frequent complication and shows itself by the presence of sand in the fæces.

The question of the relation of appendicitis to muco-membranous colitis is too important and too much a subject of controversy for me to treat of it briefly; the reader will find it dealt with in my book. The general condition is ordinarily much altered; there is a marked loss of flesh. With women troubles of the uterus or of the uterine appendages often complicate the situation. The nervous condition is always accentuated; there are various reflex phenomena (cardiac intermittences, palpitations, dizziness, attacks of dyspnœa or of suffocation, fainting fits, and the like). There is a general weakening of the nervous system, even to the point of most pronounced neurasthenia, for it must be remembered that if these patients are generally of neurotic origin the colitis, once it has a hold on them, reinforces and exalts the previous neuropathic phenomena.

Such is, in outline, the sketch of this tedious disease, the treatment of which I now proceed to consider in detail. There are some fundamental precepts which dominate the therapeutics of the disease. The practitioner must make sure that the patients have a diet suited to the state of their intestine. He should be most careful to keep the bowel open and to procure by appropriate artificial means the evacuation of the residuum that the bowel, owing to its atony, is incapable of expelling by itself. He should also attempt to modify the intestinal catarrh and, to a certain degree, the fundamental neuro-arthritic diathesis. There are three principal therapeutical means corresponding to these three indications; they are rather of a hygienic than of a medical character, and I now proceed to examine them successively. They are (1) the alimentary regimen; (2) the washing out of the intestine, and (3) the hydro-mineral treatment.

1. *The question of diet* is here of supreme importance. The problem consists in nourishing the patient in such a way that the excrement shall neither be abundant nor irritating. The food should be chosen from amongst the following aliments: milk, meat soups (chicken and other) with every particle of fat taken off, beef-tea, porridge made of barley, oatmeal, maize, ground rice, arrowroot, raccahout, &c.; eggs, boiled, scrambled, or in custards, but neither fried nor as omelets (as fat is to be avoided); white light fish—i.e., sea fish boiled, or if fried the skin and all the parts imbued with fat should be taken away; finely minced, very lean roast and boiled mutton or beef or veal or chicken; sweetbreads and brains. Vegetables mashed very fine and passed through a sieve may be given. As a rule it will be found best to give only dry pulse vegetables, such as dry haricot beans, peas, and lentils; mashed potatoes may also be given, *but on no account should any green vegetables be allowed;* for it has been remarked that as a rule the greater number of persons affected with colitis do not digest green vegetables. Even when finely chopped they pass through the intestinal tube and thence into the fæces without having been through any digestive action; they are expelled in the same state as they were eaten. Besides which, the consumption of green vegetables does not, as is sometimes supposed, diminish the constipation in the least degree. Nor can the daily enema or laxative be dispensed with because green vegetables form part of the diet. The part which they are said to play as "balai de l'intestin" is quite an illusion in the cases we are dealing with. Not only are they useless—they are harmful, inasmuch as they encumber and fatigue the already jaded atonic intestine by stagnation, producing fermentation and thus increasing the catarrh, the irritation, and the glairy secretion. Therefore it is necessary to forbid rigorously all spinach, cabbages, salads, and all raw fruits (exception to be made in those rare cases where experience shows that they are tolerated and normally digested and assimilated). Stewed or baked fruits without skins may be allowed, also boiled and baked batter puddings and custards. Very little bread should be taken and that little should be eaten stale or toasted dry. Wine and all alcoholic drinks should be absolutely banished. Alcohol acts like a poison on the intestinal canal and is always harmful. The best drink is pure, fresh, spring water or a very light table beer mixed in equal parts with a slightly mineralised table water. Milk does not suit all stomachs; it frequently disagrees when it is given in too large quantities at a time, but given moderately, associated with the above regimen, it is generally digested and it has rarely to be excluded from the patient's bill of fare. All fatty matter should be strictly forbidden and all pork except very lean ham. No game, crabs, lobster, crayfish, or other crustaceans should be allowed. All hashes, stews, rich gravies, sauces, and pastry of every kind should be forbidden. In serious or inveterate cases greater severity still is needful. Patients should in these cases take nothing but milk (if tolerated), light cereal porridges, eggs, beef-tea, and sometimes a very little finely minced raw meat. In cases where milk is not digested warm infusions such as those of camomile and lime tree bark may be given. They are very comforting in cases of dilatation of the stomach or of dyspepsia. Bread should be strictly forbidden in these cases or should only be given in very small quantities in the form of rusks or dry breakfast biscuits.

2. *The washing out of the intestine.*—The means which I consider the least harmful to the patient for resisting the intestinal atony—independently of the special modification

---

[1] *Muco-membranous Entero-colitis.* By Maurice de Langenhagen, M.D., Consulting Physician at Plombières. London: J. and A. Churchill. 1903.

which it exercises on the mucous membrane—is the methodical and carefully calculated irrigation of the large bowel, an irrigation that is to be as complete as it possibly can be. I am not unaware that in recommending this means I am tilting at a prejudice against the use of enemas that is widely spread in England. But I must repeat, the bathing of the intestine, as I understand it, is not a simple "enema" destined only to assure the evacuation of the rectum. If this were the only object in view one could let each person follow his personal preference and adopt one of the numerous well known laxatives, even though they might have the disadvantage of fatiguing the stomach, of sometimes causing colics, and of losing their effect in the end. Of these laxatives the one that I prefer is castor oil in small doses (from one to two teaspoonfuls); then there are cascara sagrada, calomel, euonymin, belladonna, podophyllin, rhubarb, and magnesia. Abdominal massage can also be employed and electrical applications, but we must remember that these last have often only a momentary effect and that if the patient is obliged to use them repeatedly they become too expensive to be within the reach of everybody. As regards the enemas of olive oil (from 50 to 200 grammes taken at night when going to bed and retained the entire night), they are generally insufficient in themselves to empty the bowel and in addition a water enema is obliged to be given the next morning. But it cannot be too often repeated, the expulsion of the fæcal matters is not the sole object of the intestinal irrigation, which has for its aim and effective result the cleaning out, the scouring so to speak, of the intestine by ridding it of the mucus and the false membranes which stay in its folds and adhere to its walls. This irrigation has even the effect (by bringing in contact with the intestinal walls a warm liquid endowed, when the irrigation is done at certain thermal resorts, with special properties that either reduce the congestion or, on the other hand, stimulate the muscular tissue) of re-awakening the contractibility of these walls, of modifying the mucous membrane, and of influencing the secretion of the glands—in one word, of doing not merely a mechanical work but a modifying work that is really curative and therapeutic. *The intestinal bathing should therefore be considered as a real internal dressing of the mucous membrane* and this explains why it is suitable not only in the cases of colitis with constipation but also in those cases where there are alternations of constipation and of diarrhœa or in cases of chronic diarrhœa. It goes without saying that I only allude to intestinal bathing correctly performed and that I have no wish to take up the cudgels for these bathings badly done—e.g., with too strong a pressure or an exaggerated quantity of liquid. As far as that goes the technique of these irrigations is simple enough and after the first few times the patient can easily acquire habitude to them. In the most ordinary case—that of muco-membranous enteritis in a chronic form, without any great contraction and with obstinate constipation and an abundant glairy secretion—this is how I proceed.

The irrigation is given by means of a fountain-injector containing two quarts and fitted with a long indiarubber pipe, from one metre 50 centimetres in length to two metres, and terminating in a supple cannula of red indiarubber, from 30 to 40 centimetres in length and from ten to 12 millimetres in diameter, pierced near the extremity by two holes, lateral and opposite to one another, so that if one of the orifices becomes stopped up by a plug of fæcal matter or mucus the other remains free. The injector should be placed at a very slight height above the bed on which the patient lies—at the most at from 25 to 60 centimetres—so that the pressure is extremely low, and the tap should be only slightly opened, so that a very slow discharge of the liquid (about ten minutes for a quart) may be assured. The water used for the irrigation should be water previously boiled, to which can be added or not some softening substance, such as linseed, marsh-mallow root, or some medicated substance, such as boric acid, naphthol, ichthyol, &c. The water should be of a temperature varying from 35° to 48° C. A temperature of about 35° C. is best suited to cases in which there is a tendency to spasm and to "resistance" on the part of the bowel; the temperatures of 45° C. and above are most useful when there is complete atony without spasm and where the physician is desirous of stimulating the muscular tissue and re-awakening the contractibility. The quantity of water to be injected varies from one quart or even less to one and a half quarts, according to the patient's power of tolerating it and the extent to which he can accustom himself to it. The patient should be lying on his back at the beginning of the operation, should then turn slightly on his right side, and should finish by lying entirely on his right hip so that the liquid penetrates to the furthest parts of the colon. For it is these furthest parts—the end of the transverse colon, the corner between the ascending and the transverse colon, and the cæcum—that the fæcal matters choose for accumulating in; and there, most often, is to be found the principal seat of the catarrhal inflammation and the most active centre for the production of the mucoid matter or membranes. Hence it is there that the cleaning process should act. It is for this reason that I always recommend if possible the arriving by degrees at large quantities of liquid, but I only increase the quantity when the patient is well accustomed to the previous dose. On principle I begin with three-quarters of a quart and augment progressively up to one and a half quarts or at the maximum one and three-quarter quarts at a time. As a general rule I prefer that the patients should have two consecutive irrigations, the first destined to rid the bowel of its fæcal contents and the second to carry away the mucus and act on the mucous membrane previously cleaned. The first irrigation should be expelled after one or two minutes and the second after nine or ten minutes if possible. But in many cases when the patient can obtain a stool before the operation (and this is an attempt always to be recommended) or when there is only a small quantity of mucus to be evacuated, or when the fatigue that ensues after the irrigation is too much accentuated, I content myself with one irrigation. For the same reasons, instead of one *séance* every day, the operation may be performed only two or three times a week. All this is an affair of tact, of degree, and of individual indications. It cannot be too much insisted on that here I only cite the average, that the prescription for the irrigation is not universally applicable, and that the different conditions of pressure, of temperature, of quantity, and even of the nature of the liquid injected should vary notably, according to the particular form and degree of intestinal atony, according to the tolerance of the patient, according to his neurotic condition, and according to the action which the physician wishes to obtain: simple evacuation of the fæcal matter, antiseptic cleaning of the intestinal canal, awakening of the contractibility and of the energy of the muscular fibre, calming of the spasms and of the contraction, reducing of the pain, and modification of the catarrhal condition of the mucous membrane.

Objections have, however, been made to the method of intestinal irrigation but I consider the greater part of these criticisms much exaggerated. Still, as they have a specious appearance which has appealed to a certain number of medical men it is necessary to examine them in detail. I do not pretend that the method I recommend is perfect; I simply state that its disadvantages are in a minority compared to its advantages. I willingly recognise the fact that a certain number of persons are incapable of supporting the large intestinal irrigations which provoke, in their case, various troubles—very violent pains, nausea and vomiting, cold sweatings, sometimes even cardiac accidents and a state of syncope. But I must add, at once, that the number of these exceptional patients is extremely limited (hardly 3 per cent. in a total of several thousands). When the physician does meet with such cases it is evident that he must do without the irrigation. But this is no reason for depriving the large majority of other patients who are capable of supporting them. Is there one medical man who would give up the systematic use of drugs like iodide of potassium, antipyrin, belladonna, and the like, because some few persons cannot tolerate them? He would first make the attempt, ready to abandon it on perceiving some special idiosyncrasy; and it should be the same thing with the intestinal irrigations.

Treating these exceptional cases apart it has been said that the washings out, even when they are tolerated, have the disadvantage of dilating the bowel, of provoking spasm and contraction, of increasing the irritation of the mucous membrane and the production of glairy matters and of keeping up, and even adding to, the state of intestinal atony by not allowing the patients to do without them. There are almost as many errors and exaggerations in these propositions as there are words, for it is *very rare to* find spasms and contractions of the bowel provoked by the irrigation. The contracting and shrinking of certain segments of the intestine, like the atonic dilatation of certain others, are normal phenomena in muco membranous colitis, and they are seen just as much among the patients who do not use the irrigations as among those who do, which proves that it is an effect of the disease itself and not of the treatment applied. If, nevertheless, the irrigations do seem with some persons to augment the spasm and provoke painful phenomena, that is because more often than not they are given *with exaggerated pressure or with a too great quantity of* liquid. Given correctly, as I indicated above, they hardly ever provoke any noticeable pain. Still, one does sometimes observe a contraction, limited to the sigmoid flexure, and entirely due to the introduction of the cannula and to the local reaction it causes. A good means of avoiding this partial spasm consists in smearing the cannula with a pomade with belladonna or cocaine in it instead of simple vaseline. Just consider, how could the intestine be "dilated," that is to say, how could its walls be forced by the introduction at *low pressure of a liquid which never completely fills* the cavity which receives it? Take a pig's bladder and fill it by degrees with water. So long as this bladder is not swollen, until the liquid presses on its sides they will not be distended, nor suffer elongation, nor forced dilatation. Well, to fill the large bowel so as to distend it from the rectum to the ileo-cæcal valve we should need at least, according to the experiments made on dead bodies and living ones, from three to four quarts of liquid, and, as we have seen, we never inject more than one and three-quarter quarts at a time. Can it be admitted that this very moderate quantity of liquid which as it increases spreads itself without obstacle into the furthest portions of the intestinal tube can distend its walls, even allowing for the distension produced by the gases, which themselves, perhaps, partly dissolve in the liquid introduced, partly get through it, and are expelled with the residue of the irrigation?

Again, it is an absolute error to pretend that the washings out irritate the intestinal mucous membrane and increase the catarrh. This might be so if astringent or caustic solutions were used, but performed with water charged with softening substances or with mineral water of sedative properties they produce no irritation at all. The best proof is that the irrigations never cause an expulsion of glairy and mucous matters from persons who do not habitually expel them. This is an experiment that I have tried several times on healthy persons or patients suffering from simple constipation without accompanying colitis and always with the same negative result. We may conclude, then, if we find among patients suffering from colitis a larger quantity of mucous matter after the irrigations than at other times, that the mucus accumulated in the intestine, remaining there for some time and causing by its presence an intensification of inflammation, is expelled in larger quantity by the effect of the irrigation, for the well-being of the patient; they are already old productions and not new ones, which on reflection it will be seen could not form up instantaneously and suddenly.

The last reproach made against the irrigation, that of keeping up and sometimes augmenting the intestinal atony, contains more truth than the preceding ones. But I think this disadvantage makes itself but [illegible] greater number of patients [illegible] lost when the treatment by [illegible] these patients never went spontaneously to stool and only obtained evacuation of the bowel by a daily dose of cascara or castor oil. Consequently, with such patients the intestinal atony has not been increased by irrigation, seeing that it was at its worst before. Even supposing that some patients who had not yet lost all intestinal *strength and who still had some spontaneous stools* before the treatment by irrigation had while curing the catarrh (and all the inconveniences it causes, pains, nervous reflex phenomena, &c.) abolished what still remained of the function [illegible] very small compared [illegible] I therefore conclude [illegible] employment of intestinal irrigation is the chosen method for the treatment of colitis and that the greater number of the objections formulated against it are imaginary and without value, the only real one applying to a very limited number of patients. The total of cases in which the irrigations are useless or cause slight inconvenience certainly does not exceed 20 per cent., according to my statistics; and it seems to me the study of medicine should in strict duty concern itself with a therapeutical process which can count success in the proportion of four-fifths.

3. The third method of treatment of colitis is a hydromineral cure judiciously chosen. As far as my knowledge goes there does not exist in England a suitable resort for treating this disease. In France two resorts are now in vogue—Plombières and Châtelguyon. But their composition is widely different. Châtelguyon possesses *temperate springs* (27° C.) *with bicarbonate and salt*, slightly laxative and tonic. Plombières, on the other hand, possesses hypo-thermal springs (up to 72° C., average 50°) with bicarbonate and silicate of sodium, slightly arsenical. The waters were known to antiquity in the treatment of rheumatic affections and of diarrhœa of an arthritic or tropical origin; their employment for colitis is more recent in the same way as the knowledge of the disease itself. The consumption of the Plombières water by drinking produces neither constipation nor diarrhœa, *still after the cure a diminution of constipation is generally* noticed. In addition these waters are essentially sedative to the nervous system and reduce the congestion of the intestinal mucous membrane. It is to this triple property (general anti-rheumatic action, nervous sedative, and reduction of local congestion) that they owe their growing success in colitis—a disease, it should not be forgotten, of an essentially nervous and arthritic origin. Plombières, therefore, attacks the origin of the harm by modifying the constitution of the subject. Châtelguyon, on the contrary, is more efficacious against the symptom constipation. That is why I advise sending above all to Châtelguyon patients who are suffering from simple constipation without intestinal catarrh or with very little of it. Whenever the catarrh is intense and when the painful, neurotic, or neurasthenic phenomena are pronounced Plombières is preferable. When it is a question of the diarrhœic forms hesitation is not permissible—it is Plombières that should be chosen. One of the great advantages of Plombières on which I must again insist is the perfection of the apparatus for intestinal irrigation. This apparatus was established six years ago under my instructions. It consists of a bed with a mattress pierced by a basin with a hole for the escape of the fæcal matter and an irrigator of elongated form and of sufficiently large capacity in direct communication with the reservoirs of the thermal water. This irrigator is fitted at its inferior extremity with an indiarubber pipe to which can be adapted the patient's cannulas and is moveable the length of a graduated scale which serves to regulate the pressure. On its exterior it has a thermometer and a water-gauge graduated *in quarts, half quarts, and quarter quarts.* All the conditions of temperature, of pressure, and of quantity can be minutely regulated by the medical man and executed by the *employé* in charge of the apparatus and by the patient. This apparatus has been copied in other French thermal resorts, but they are less numerous and less generally employed than at Plombières. Thus Châtelguyon is, above all, a place where the patient drinks the water; Plombières, above all, a place where he takes baths and [illegible] at this resort has the great [illegible] *to perform the irrigation;* [illegible] Plombières by the constant [illegible], by the imitation of his neighbours, just as in a sanatorium the tuberculous patient learns the rest cure and the cure by aeration and over-nourishment and is able when he returns home to continue it because he has understood its importance and realised its practice.

But intestinal irrigation is not the only means in use at Plombières. By the baths the general nervous system is *affected*, is calmed, and the secretive activity and the painful phenomena are modified; by a wisely arranged hydropathic treatment the impoverished general nutrition is stimulated and the whole organism tonified. Lastly, massage, abdominal and general, is very often prescribed either to stimulate intestinal atony or to exercise a general tonic action. Kissingen has also a certain reputation in the treatment of intestinal diseases. But I consider this resort above all suitable in cases of diarrhœa, or, like Châtelguyon, in cases of simple constipation without a concomitant catarrh. For they are, in fact, cold salt waters exercising rather a tonifying, general, and local action. They are employed exclusively for drinking and bathing, the intestinal irrigations being unknown there. Vichy and Carlsbad can also be recommended, but with a great deal of prudence. I consider it an error, too often perpetrated, to send to these stations habitual cases of colitis and I have more often than not seen patients suffer bad effects from them. They are only suited to cases where the dyspeptic or hepatic symptoms which exist at the same time as the intestinal phenomena are very pronounced; in that case a cure at Carlsbad or Vichy can alternate with a cure at Plombières or Châtelguyon.

Such are the three principal elements—a veritable therapeutic tripod—of the treatment of muco-membranous colitis. As may be seen, the means are exclusively hygienic, and what may properly be called drugs have not much to do with this treatment; they are almost always inefficacious, and sometimes even harmful, owing to the alcohol or other irritating substances that are often mixed with them. The physician is, however, obliged to fight against the painful phenomena that accompany colitis, for the patient asks for some relief. To this end belladonna in the form of suppositories should be used, or taken internally in the form of tincture or pills (one grain of the extract in five or six pills for every 24 hours), or frictions with an ointment containing mercury and belladonna can be given if a calming effect is desired, or with turpentine if a somewhat stimulating action is preferred. Very hot, large poultices, sprinkled with laudanum, placed on the abdomen also succeed very well; or in the same way applications of large compresses dipped in a very hot decoction of poppy-heads, covered over with impermeable taffeta and with strips of flannel, and kept on the entire night. Indian hemp calms the intestinal spasms very well. A good elastic belt is necessary to hold and to lift up the abdomen in patients who have noticeable enteroptosis. The physician should be chary of using drugs against the dyspeptic phenomena that accompany colitis, since generally these troubles are lessened as the state of the intestine improves; but, according to the case, a little hydrochloric acid may be used, or alkalies, absorbent inert powders (charcoal, chalk, magnesia), and nux vomica.

ON THE REMOVAL OF THE GALL-BLADDER IN OPERATIONS FOR GALL-STONES.

By B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

IN 1902 I read a paper entitled "A Series of Cases of Cholecystectomy" before the Yorkshire branch of the British Medical Association. I gave then the following indications for the performance of this operation: (1) in injuries of the gall bladder, rupture, stab, or bullet wounds; (2) in gangrene of the gall-bladder; (3) in phlegmonous cholecystitis; (4) in membranous cholecystitis; (5) in chronic cholecystitis with dense thickening of the walls of the gall-bladder and cystic duct, with or without stenosis of the cystic duct, and in chronic cholecystitis when the gall-bladder is shrivelled and puckered and universally adherent (in such cases it is no longer a receptacle for the bile); (6) in distension of the gall-bladder, hydrops or empyema, due to blockage of the cystic duct by calculus, stricture, growth, or external inflammatory deposits, or in cases of mucous fistula following operations for these conditions; (7) in cases of fistula between the gall-bladder or the cystic duct on the one hand and the stomach, duodenum, or colon on the other; (8) in multiple ulcerations of the gall-bladder or the cystic duct when gall stones have eroded their way through the walls into the liver, the duodenum, or other protective adherent masses; and (9) in primary carcinoma of the gall-bladder. The result of my early cases was so satisfactory that I was led to put the operation to a more extended proof and as my experience increases I am tempted to ask whether it would not be the better treatment in all, or in nearly all, gall-stone operations to remove the gall-bladder entirely. The experience of every surgeon who has worked extensively in this field of surgery is that the chief purpose and the main indication in any operation for gall-stones is the drainage of the gall-bladder and bile-ducts. Of the validity of this experience there can be no question. We know that gall stones are rendered troublesome by the cholecystitis or the cholangitis which they are the means of arousing. In many cases it is because of the inflammatory consequences that an operation is demanded. The essential part of any operation would therefore seem to be the drainage of the gall-bladder, prolonged for such a time as to allow a complete subsidence of the inflammatory process. But in the very great majority of cases the secondary inflammation has its origin and runs its course entirely within the gall-bladder; an infection of the hepatic or common ducts does not occur. In many cases, therefore, in removing the gall-bladder we are doing away with the necessity for drainage by removing that structure the drainage of which seemed imperative. It is within the gall-bladder that the great majority of stones are formed; it is within the gall-bladder that the secondary inflammatory troubles break out and are, in the majority of cases, altogether limited. The removal of the gall-bladder, therefore, does away with the need for drainage. It renders less likely the formation of gall-stones and it renders less likely the inflammatory consequences of their presence. If, however, the need for drainage is absolute it is possible, in fact quite easy, to drain the ducts after the gall-bladder has been removed. After the division of the cystic duct the stump of the duct may be slit up until the hepatic duct is reached or the cystic duct may be cut off flush with the common duct. It is then quite a simple matter to explore upwards and downwards with a spoon or with the finger to make certain that the ducts are clear of calculi and then to stitch in, by a single catgut suture, a rubber drainage-tube. The presence of stones in the common duct does not debar one from removing the gall-bladder. In two cases I have removed stones from the ampulla of Vater by duodeno-choledochotomy and have then at once removed a chronically inflamed gall-bladder full of stones and, after dividing the cystic duct close to the common duct, have drained the latter with a rubber tube. Both patients recovered without the slightest interruption. The plea therefore that the need for drainage is opposed to the routine removal of the gall-bladder is answered by the fact that when the gall-bladder is removed the need for drainage does not often exist, as that need was due to the presence of the gall-bladder, and by the fact that if drainage of the ducts is desirable or necessary it can be carried out without the smallest difficulty.

An examination into the recorded cases of carcinoma of the gall-bladder and of the adjacent portions of the liver shows that in approximately 95 per cent. (Siegert) the malignant change is due to the chronic irritation of gall-stones. If the gall-bladder is removed there will, of course, be no chance of this malignant growth occurring. This is not, however, a point of much importance, for the cases of carcinoma are those in which no operation has been done; by the time the surgeon sees the case the growth is already there. To make the argument for cholecystectomy a strong one from this point of view it would be necessary to show that malignant disease occurred after cholecystotomy, and so far as I know this has not been done.[1] In the very great majority of operations for gall-stones there is ample evidence of long-standing inflammation in and about the gall-bladder. The normal smoothness of the gall-bladder is gone, its deep blue colour is lost, and its supple walls have become thickened and tough. A glance at a gall-bladder during other abdominal operations will tell one in a moment whether stones are lying there. If the gall-bladder is blue it is healthy; if opaque and grey or yellow there are, or there certainly have been, stones and a chronic inflammation aroused by them. In many cases, therefore, it will be concluded that cholecystectomy is the more desirable operation, but before its routine adoption is advocated it is necessary to show that the gall-bladder is useless and that its removal does not add any risk as compared with cholecystotomy. In the abstract one might be inclined to think that the loss of a bile reservoir capable of emptying on demand would be a serious matter to the individual or at the least a disability. The perfection of the mechanism of digestion so graphically told by Pawlow would seem to require that bile should be ejected in spurts, as it were, into the duodenum during digestion. But there is clinical experience in abundance to show that when all the bile is discharged from the body through an external biliary fistula, without a drop entering the intestine, the individual suffers no sign of disability of any kind. There is abundant evidence also, furnished by my own cases and by many others, to show that the removal of the gall-bladder does not interfere with digestion, that the individual eats well, gains in weight, and to all appearance has the same duodenal digestion as an ordinary healthy individual. The gall-bladder, therefore, if not useless, can quite well be spared.

---

[1] A case of [illegible] after cholecystotomy has been rece[illegible] R. Lawford Knaggs in THE LANCE[illegible] p [illegible]

The removal of the gall-bladder does certainly not involve a greater risk than the operation of cholecystotomy. I have, in fact, in several cases been convinced that the removal of the gall-bladder made the operation simpler and shorter than it would have been if a multitude of small stones had been removed. By carrying out the operation in the manner described below it will be found a safe, speedy, and simple procedure. During the last two years I have inclined more and more to the *performance of cholecystectomy, and after* some hesitation and some trepidation, which experience has removed, I am strongly disposed to advocate the frequent, though not the invariable, adoption of this operation in preference to cholecystotomy. Its advantages are that the operation removes the chief source of the disease, that it thereby prevents in great measure a recurrence either of stones or of the inflammation which betokens their presence, that growths in the gall-bladder or adhesions around it are *subsequently impossible, and finally, that the wound, if* drainage is not required, may be caused to heal throughout by first intention. The gall-bladder is devoid of any strikingly useful purpose and its removal does not add to the danger of the operation. If drainage of the ducts is necessary it can be carried out quite satisfactorily. The presence of a stone in the common duct does not prohibit the operation, but drainage of the duct, after removal of the stone in the duct or in the ampulla, is necessary. The one *disadvantage that* may justly be urged against cholecystectomy is this: that if a late operation should become necessary—for stones can, and do, form in the hepatic and common duct—such an operation would be more difficult and almost certainly more dangerous. The possibility of a further operation being necessary cannot be denied but the likelihood of it is negligible. The list of conditions demanding cholecystectomy given at the beginning of this paper may therefore be considerably increased and made to include all cases, or almost all cases, of gall-stone disease requiring surgical treatment.

The operation of complete cholecystectomy is performed in the following manner. A vertical incision near the outer margin of the right rectus muscle is made and the muscle fibres are split. The usual length of this incision is five inches. If additional room be required it is best obtained by continuing the upper end of the incision along the costal margin upwards and inwards. All adhesions of the gall-bladder and ducts and liver having been cleared, the liver is rotated by gentle traction upon the gall-bladder until the cystic and common ducts are straightened and brought upon a level with the wound. By this manœuvre the operation is rendered simpler and quicker. The gall-bladder may now be removed from before backwards or from behind forwards. Latterly I have preferred to divide the cystic duct and to secure the cystic artery before freeing the gall-bladder. By dragging upon the gall-bladder the cystic duct is made clearly discernible. Its peritoneal investment is divided and stripped up along the duct towards the hepatic and common ducts, so that a cuff of peritoneum is raised up from the cystic duct. The latter is divided after securing it with a catgut ligature and the cystic artery is also defined and secured. The peritoneal cuff is then turned over the divided end of the duct and sutured. If it is intended to drain the common duct no ligature on the cystic duct is necessary. The cystic duct is cut off at its junction with the hepatic and common ducts and into the opening that is left a rubber drainage-tube *is stitched.* The gall-*bladder is* then stripped up from behind forwards. The separation from the liver is readily effected by stripping up with the finger around which a thin strip of gauze is rolled. The peritoneum which passes from the liver to the gall bladder is cut with scissors about three quarters of an inch away from the liver, so that after removal of the gall-bladder the bared surface of the liver may be covered in by peritoneum. There is occasionally some bleeding from the denuded liver. This is readily checked by a suture or by the firm pressure of a hot swab or sponge. If the common duct is drained it is well to put in two other drains, one to the inner side of the duct towards the duodenum and one to the outer side towards the kidney pouch. These drains, whether of gauze or of rubber tubing, should be stitched in position by one or more sutures of catgut and they are left in for from eight to ten days. At the end of this time their removal is quite easy. It is necessary to stitch them in position in order to prevent them being moved away within a few hours on account of the constant movements of the liver during respiration.

Leeds.

NOTE ON THE CAUSES OF COUGH IN CHILDREN.

BY ARTHUR W. FULLER, M.D. EDIN.,
RESIDENT MEDICAL OFFICER TO THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, LONDON.

THERE are many cases of ill-health occurring amongst children in which, although cough is a persistent symptom, the physician is unable to detect any abnormal physical signs in the chest and the usual expectorants are exhibited in vain. There is frequently vomiting in these cases and wasting and weakness may become so marked that life may be despaired of. The severer forms have been often called "consumption" or "decline," while the milder have received the names "bronchitis" or "bronchial catarrh," whereas, as I have indicated, neither the lungs nor the bronchi are at fault. Those cases where the cough is accompanied by spasm and a consequent "whoop" are put down at once as whooping-cough, may be treated as such for months, and *frequently serious chest trouble ensues. Their* non-infectious nature should be sufficient to guard against this error. In the large majority of these cases it is to the back of the throat, the tonsils, the fauces, and the pharynx that we must go for the *fons et origo* of the condition. A very slight degree of pharyngitis, of tonsillitis, or of adenoid growths in the naso pharynx may produce cough in a child the reflex activity of whose nervous system is high. I desire to point out the frequency of the occurrence of one or other of these conditions in children suffering from cough and to recommend that the throat at least should be examined in every case.

Adenoid cough has been recognised for some time although in the existing text-books on diseases of children it scarcely receives the place it deserves and in some it is not even mentioned. Of 621 consecutive cases of cough which I have treated during the past two years, most of which were supposed by the mothers to be whooping cough and were brought to the Royal Waterloo Hospital as such, no less than 371 of the patients were suffering from tonsillitis, pharyngitis, or chronic enlargement of the tonsils, or from post-nasal adenoid growths in a greater or less degree, and most of them lost their cough entirely when the throat was put in a satisfactory condition. This proportion is high and probably is not applicable to many places outside London, or even to the healthier parts of London, but amongst the children living in the poorer districts of this city inflammatory conditions of the pharynx, *tonsillitis,* and adenoids prevail to an enormous extent, and it is a serious question for the Commission appointed to inquire into the causes of the alleged physical degeneration of our race what part enlarged tonsils and the presence of adenoids contribute to that result. At the Infirmary for Children in Liverpool the proportion of these cases was not nearly so high, due, in my opinion, to the different atmospheric conditions prevailing. The heavy, foggy atmosphere of London, holding, as it does, much organic *matter and micro-organisms in* suspension, especially in low-lying and overcrowded districts, would appear not only to initiate but to keep up a chronic irritation of the mucous membrane of the throat and pharynx, aided by an insufficient amount of vigorous exercises and the consequent enfeeblement of the circulation and defective development of the breathing apparatus. The great desiderata from this point of view are more and larger open spaces where children may be allowed to play and realise *that they are really children* (and not, as it were, pocket editions of men and women), where they can flush out their air passages with an approach, at any rate, to pure air and thus counteract to some extent the pernicious effects of the atmosphere in which they must perforce live and work.

The medical treatment should be on the following lines. In cases where there are signs of any acute inflammation and where there are no obviously enlarged tonsils or adenoids present the back of the throat should be treated antiseptically, in the older children by gargling, in the younger by spraying; sometimes chlorate of potassium given internally has a good effect and also various antiseptic lozenges may be given. If anæmia be present iron should be prescribed. Sedatives are often necessary to counteract the extreme reflex irritability and the *habit of cough* that is sure to have been formed. The bronchi may be affected secondarily and then it may be necessary to administer one or other of the ordinary expectorants. If not much debilitated, instead of being kept quiet indoors, the child should be encouraged to take vigorous exercise in the form of games in the open air. For girls the use of the skipping rope is a valuable exercise. Where practicable change of air is to be recommended and, indeed, may be the only treatment required in mild cases. Where there are adenoid growths present or markedly enlarged tonsils they should be removed as soon as possible, followed by the treatment detailed above. Carious teeth should also be attended to, for the throat is frequently infected from them In some of these cases the cough departs immediately after the operation. A case is before me of a child who had a distressing cough for four months; the adenoids were excised on June 27th and by July 10th the mother merely came up to the hospital to report that the cough had entirely ceased and that her child was perfectly well.

Waterloo-road, S.E.

A CASE OF ATTEMPTED DIVISION OF THE EIGHTH NERVE WITHIN THE SKULL FOR THE RELIEF OF TINNITUS.[1]

BY CUTHBERT S WALLACE, M.B., B.S. LOND., F R C.S ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL, IN CHARGE OF OUT-PATIENTS; ASSISTANT SURGEON, EAST LONDON HOSPITAL FOR CHILDREN,
AND
H. J. MARRIAGE, M B., B S. LOND., F.R C.S. ENG.,
LATE SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL.
(*With a Report on the Resulting Degeneration by* DR E. FARQUHAR BUZZARD, *Pathologist to the National Hospital, Queen square; Assistant Physician, Royal Free Hospital.*)

THE patient was a female, aged 23 years. In February, 1898, she developed left otitis media which was quickly followed by a mastoid abscess. The abscess after being opened soon healed but the discharge from the ear continued. In October of the same year the mastoid was opened and a more or less complete operation was performed. The result being unsatisfactory, in July, 1899, and again in March, 1900, the patient was admitted to St. Thomas's Hospital and more bone was removed; on the latter occasion the cavity was grafted. In spite of this the discharge continued, necessitating a further removal of bone and granulations in December, 1901 On this occasion also the unhealed surface was covered with Thiersch grafts. After this operation the discharge ceased and the whole cavity completely healed. For a year all went well but at the end of this period pain was experienced in the posterior part of the mastoid process. In addition to this the patient began to suffer from tinnitus and vertigo. On admission on August 18th, 1903, she was anæmic and complained of giddiness, noises in the ear, and a pain over the left mastoid and in the course of the small occipital and auriculo temporal nerves The external auditory meatus and the middle ear were represented by a large smooth cavity lined with healthy white skin. The bony labyrinthine wall was intact. One of us made the following note of the condition of the left ear. "When speaking in a loud tone directly into the left ear, after closure of the right, sounds are heard but no words can be distinguished. A loud-ticking watch is heard only when placed in contact with the remains of the left mastoid. On the right side the same watch is heard at a distance of 24 inches. A tuning fork placed on the forehead is heard on the right side only; when placed on the point of the chin the fork is heard slightly on the left side but quite distinctly on the right; the tuning fork is not heard at all when held immediately opposite the left meatus and only just heard when placed on the left mastoid. In the right ear the air conduction is considerably better than that of the bone, though slightly shorter than normal. The noises in the ear ceased on compression of the left common carotid artery." There were two tender spots behind the ear: one at the junction of the posterior border of the mastoid process with the skull and the other at the lowest part of the same border. The amount of tenderness varied considerably but could always be elicited on pressure. There was no œdema or sign of acute inflammation. The pain radiated in the distribution of the small occipital and auriculo temporal nerves but its severity varied greatly. The tinnitus was entirely confined to the left ear, sometimes being compared to the rushing of water, at others to the sound of bells; it was always present but was most noticeable at night, especially if the patient lay on the left side. Its severity had increased to such an extent that sleep was seldom obtained without the use of hypnotics and even with these it was broken and disturbed. The vertigo was of the type usually met with in Ménière's disease; when an attack occurred the ground seemed to rise towards the face of the patient. There was no inclination to fall to one side or the other, nor did objects appear to pass from left to right or *vice versâ*. The patient never dared to venture outside the house without a friend by her side.

The general condition of the girl was pitiable and it was evident that unless something was done she would soon be worn out by want of rest. She was quite convinced that the causes of her trouble were the noises in the ear and that compared with these all other symptoms sank into insignificance. Drugs were tried with absolutely no result and it seemed that the only recourse left was division of the auditory nerve, for we decided that, although the noises ceased on compression of the common carotid artery, it was not advisable to ligature that vessel since the results obtained by this operation were not satisfactory in the cases reported by Meyerson[2] and Grunert[3] (in the former case the noises returned after four hours and in the latter after four months), while in the case reported by Linsmayer,[4] who ligatured the external carotid artery, the noises ceased only for a short time, but hemianopsia and deafness of the same side with hemiplegia of the opposite side developed, and at the necropsy on the patient, who died on the fifth day from pneumonia, extensive recent softening of the hemisphere was found. With this end in view we undertook numerous experimental operations on the cadaver.

There are two routes through which the auditory nerve can be reached within the skull: (1) by exposing the cerebellum in the usual way, opening the dura mater, and slowly compressing the cerebellum inwards until the facial and auditory nerves come into view; and (2) by the operation for exploration of the posterior surface of the petrous portion of the temporal bone. This is an elaboration of the ordinary operation for the cure of mastoid caries. After consideration it was decided to adopt the second of these routes. We were influenced in our decision by the fact that a large amount of bone had already been removed and also by the fact that there were still pain and tenderness at the posterior border of the mastoid process pointing to some abnormal condition in these parts.

Description of the operation on the cadaver.—The complete operation for mastoid caries was first performed, the lateral sinus being exposed and the posterior meatal wall being removed down to the level of the facial canal. The dura mater over the temporo-sphenoidal lobe was next exposed and by working backwards and downwards from this point the dura mater over the cerebellum for a distance of three quarters of an inch behind the lateral sinus was laid bare This was found to be necessary in order to gain space for retraction of the cerebellum in the later stage of the operation The portion of the temporal bone forming the inner wall of the mastoid was next removed, starting from the groove for the lateral sinus and extending forwards and inwards as far as the horizontal semicircular canal and the remains of the posterior wall of the meatus.

[1] A paper read at a meeting of the Clinical Society of London on March 25th, 1904.

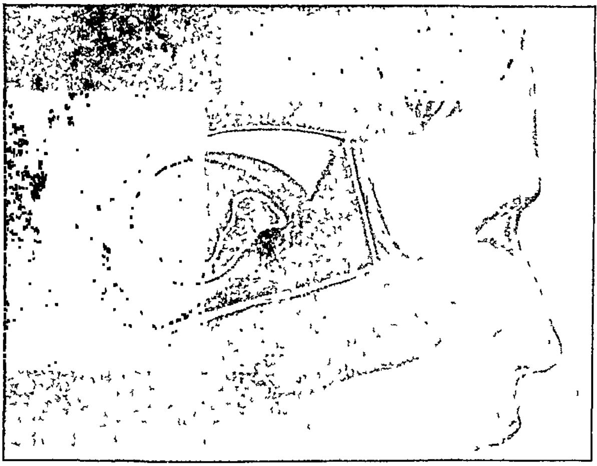
[2] Versuchungen der Deutschen Naturforscher und Aerzte, 1895.

[3] Archiv fur Ohrenheilkunde, Band xxxv.

[4] Politzer's Diseases of the Ear, fourth edition, p. 778.

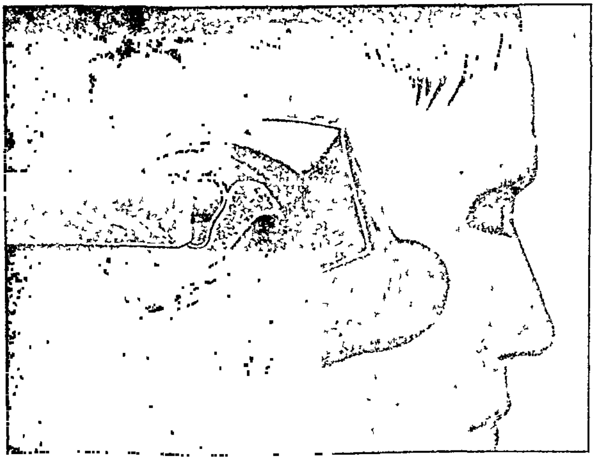
The extent of dura mater in front of the lateral sinus exposed by this means was found on an average to be three-eighths of an inch (Fig. 1). The anterior edge of the exposed part of the dura mater was then incised to the extent of about one inch. A flat retractor half an inch broad and bent on the flat to a convenient angle was introduced an [illegible] aid of a [illegible] obliquely [illegible] depth of this nerve from the cut edge of the petrous bone varied in different bodies from a half to three-quarters of an inch. Approached in this way, the facial nerve cannot usually be seen, as it lies deep—that is, internal to the auditory—but occasionally as the two nerves appear from behind the cerebellum the edge of the facial nerve can be seen just behind (above, speaking anatomically) the auditory. Pressure on the auditory nerve applied as near the brain as possible enables the facial to be brought into view; a blunt hook can then be easily passed round the eighth nerve without damage to the facial. The auditory nerve can then be divided either by traction or by the scissors. On the cadaver the operation is not difficult and

FIG. 1.



First stage of operation. The bony walls of the antrum and attic have been entirely removed. Anteriorly is seen the tympanum, T, and posteriorly the lateral sinus crossing the exposed dura mater.

FIG. 2.



Second stage of operation. The dura mater has been incised, a spatula introduced, the cerebellum pressed backwards and the auditory nerve exposed.

it only requires patience successfully to divide the auditory nerve and to leave the facial intact. We performed the operation many times and verified the result after the removal of the brain.

On Sept. 3rd the first operation was performed, it being then intended to complete the procedure at one sitting. The usual incision was made through the old scar and from the middle of this another incision was made backwards for about an inch, in order to provide for the exposure of the cerebellum. The steps above narrated were followed out except in so far as the process was shortened by the previous removal of bone. The lateral sinus gave considerable trouble; it was large, tensely distended, and protruded in such a way as to suggest that the normal flow through it was obstructed. In removing bone at the lower part of the wound and over the lateral sinus as it turned in towards the foramen lacerum posterius considerable bleeding occurred which necessitated plugging and the postponement of the operation until the bleeding ceased. The wound was therefore closed and the patient was put back to bed. The operation caused at first a considerable amount of shock but it passed off by the next morning; vomiting was also troublesome and the patient complained of pain in the region of the left ear and eye. The pulse was 100 and the temperature was 99·2° F. During the next few days her condition improved but she still suffered from headache. The noises in the ear caused her great distress.

On Sept. 10th, the pulse being 92 and the temperature 98°, the wound was reopened and the operation was proceeded with. The lateral sinus, although now filled with clot, was still very prominent. The anterior border of the exposed part of the dura mater was divided, the incision being somewhat curved with the convexity forwards. Its length was about one inch. A large amount of cerebro-spinal fluid at once flowed out. A flat bent retractor was then introduced and an attempt was made to expose the nerve; it was found, however, that sufficient room could not be gained owing to the resistance offered by the lateral sinus; this was therefore divided between ligatures. The cerebellum was next slowly pressed backwards, but a good view of the parts could not be obtained owing to the continual flow of cerebro-spinal fluid. In addition to this considerable trouble was given by bleeding which proceeded from the surface of the cerebellum. After much difficulty a view of the nerve was obtained. By means of a blunt hook the auditory nerve was pushed aside and the facial nerve was exposed. The hook was then turned through a right angle and passed behind the auditory nerve which by traction was torn across. At this moment bleeding again obscured the view but when this had ceased the divided end of the auditory nerve could be seen lying in the internal auditory meatus, while the facial, distinguishable by its small size, was seen to enter the meatus intact. As far as could be judged the operation had been successful. The wound was closed, a small gauze drain being inserted at the lower angle.

On Sept. 11th there was no facial paralysis, the tinnitus had greatly subsided but was still obvious to the patient, the temperature was normal, and the pulse was 80. The patient complained of considerable giddiness when she attempted to raise her head and also of headache. The dressings were continually soaked with cerebro-spinal fluid. On the 12th the flaps were found bulged by blood clot, some of which was let out. On the 14th the cerebro-spinal fluid was still being discharged in considerable quantities. The stitches were found to have given way and a considerable amount of blood clot to have been extruded. There was some hernia cerebelli. There was no attempt at healing in the wound. The temperature was 98·8° and the pulse was 84. Diplopia was present to a very slight degree. The headache still continued but was less severe. The patient had not rallied properly from the operation and although she complained of giddiness her state did not admit of any attempt being made to learn the exact nature of this beyond the fact that it did not trouble her if she kept quiet. There was occasional vomiting. On the 24th the general condition remained the same. The diplopia had cleared up. The flaps no longer bulged and the wound was quite clean but showed no signs of healing; the discharge of cerebro-spinal fluid continued. The headache was at times severe and required morphine. The patient no longer complained of tinnitus. The ocular fundi were normal. From this time until the day of her death her condition varied very little. She gradually lost strength and became more and more apathetic, so that no observations of value could be made. The wound never showed any reaction or made any progress in healing. The cerebro-spinal fluid continued to be discharged in large quantities. The pulse varied between 100 and 120 and the temperature between 99·4° and 97°, except on Sept. 28th when it rose to 101°. Death occurred on Oct. 1st, 21 days after the division of the nerve.

Necropsy.—At the post-mortem examination it was found that there was no meningitis at any point. The cerebrum was healthy throughout. The right cerebellar hemisphere was also normal in appearance and consistence. The left cerebellar hemisphere was somewhat soft but showed no loss of substance. The cortex was blood-stained and the vessels were full of blood. The cochlea and semicircular canals on the left side presented a perfectly normal appearance. The facial nerve was intact. The auditory nerve had been divided, with the exception of a strand as thick as a fine piece of cotton which lay next the facial nerve. The other organs were healthy except for old caseous foci at the apex of the left lung.

Report by Dr. FARQUHAR BUZZARD.—"The material submitted to me for examination included the lower half of the pons Varolii and the entire medulla oblongata; unfortunately the cerebellum had been removed from the former so that the ultimate destination of certain fibres of the vestibular nerve could not be ascertained. The whole piece was divided transversely into a number of thin blocks which were stained by the Busch modification of the Marchi method, imbedded in celloidin, and cut. The sections obtained were mounted serially and examined under the microscope with the following results briefly summarised.

About two-thirds of the fibres of the cochlear nerve constituting its entering root were degenerated, the non-degenerate fibres being distributed in its lateral and posterior part. The majority of the degenerate fibres terminated in the ventral cochlear nucleus; a very few could be traced as far as the dorsal cochlear nucleus and a considerable number turned sharply inwards and cerebrum-wards to the region of the superior olive and, *viâ* the corpus trapezoides, to the opposite side of the pons.

The whole of the entering root of the vestibular nerve was degenerated. The large majority of the fibres could be traced into the principal nucleus (nucleus nervi vestibuli medialis) or into the descending root where they could be followed in diminishing numbers as far down as a level corresponding to the middle of the hypoglossal nucleus. A smaller number of fibres broke up in the neighbourhood of Deiters's nucleus (nucleus nervi vestibuli lateralis) and a few turned directly into the corpus restiforme soon after their entry into the substance of the pons. In the absence of the lateral wall of the fourth ventricle it was impossible to say whether any fibres passed direct to Bechterew's nucleus (nucleus nervi vestibuli superioris) or into other parts of the cerebellum. In addition to the degeneration resulting from the section of the eighth nerve much recent degeneration was seen in the descending spinal root of the fifth nerve of the same side throughout its length in the pons and medulla, suggesting that the afferent portion of that nerve had been damaged in its extra-medullary course.

Finally, there was noticed a hæmorrhagic softening of the tissue immediately surrounding a small vessel which entered the pons on the medial side of the vestibular nerve and which pursued a course inwards, dorsum-wards and cerebrum-wards, without, however, penetrating as far as the corpus trapezoides. The degeneration resulting from this vascular lesion was confined principally to certain transverse fibres of the pons going to the middle cerebellar peduncle. I have seen similar vascular lesions as the result of the operation for the division of posterior roots and attribute them to accidental traction upon accompanying or neighbouring vessels."

This case shows the possibility of division of the auditory nerve within the skull without injury to the facial nerve. The chief difficulty to be feared is bleeding from the surface of the cerebellum which was encountered in this case and to which must be attributed the failure to divide completely the nerve. At the operation no remaining strand could be seen, owing, we think, to the strand adhering to the facial nerve and thus escaping recognition. The blunt hook must have penetrated the nerve in such a way as to leave this small portion behind and in attempting to sponge away the blood after the hook had been pulled out the small strand was in all probability pushed up against the facial nerve and remained in contact with it. The cause of death was not ascertained with any certainty. Probably the wretched condition of the patient before the operation was a contributing factor, as it left no reserve force properly to combat the shock of the operation and to produce a healing reaction in the wound and so to prevent the continual loss of the cerebro spinal fluid.

The case was a failure both clinically and scientifically. There was no doubt that the tinnitus was present, though diminished, for several days after the operation and it is doubtful if it really ever subsided. Taking into consideration the degeneration described by Dr. Buzzard the continuance of the tinnitus must be attributed to one of two causes: (1) that the noises are central in origin; or (2) that the causes of the tinnitus originate in the cochlea and the impulses by which they become apparent are conveyed to the brain by the cochlear nerve (the vestibular nerve was completely degenerated).

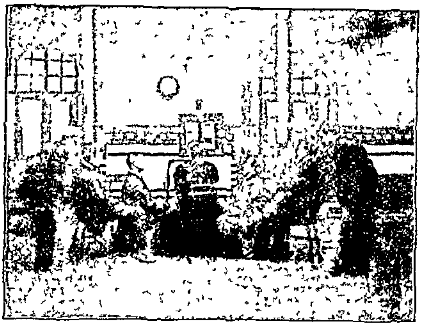
A NEW METHOD OF DEMONSTRATING THE LARYNGEAL IMAGE AND INTRALARYNGEAL OPERATIONS.

BY EUGENE S. YONGE, M.D. EDIN.,
HONORARY ASSISTANT PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.

THE practical study of laryngology appears to have been entered upon—at any rate in this country—by a comparatively small number of the profession outside those actually engaged with the subject as a specialty. The acquisition of the art of laryngoscopy has not been looked upon by the student as necessary for his academic salvation and it has therefore had a tendency to be regarded in the light of a supererogatory work. This circumstance, together with the appreciable amount of time and practical experience required to gain dexterity in laryngeal and intralaryngeal work, and the relatively infrequent occurrence of such cases in general practice, may have been responsible to some extent for the limitation of interest. But there is also the fact that the clinical demonstration of laryngeal cases, whether in the class room or at general medical meetings, has very commonly proved unsatisfactory and cases have failed to arouse the interest they deserved on account of the defective nature of the means which were available for showing diseased conditions of the region in question. It has been, and is, of course, possible for a laryngoscopist to demonstrate the laryngeal image, as it were, "over his shoulder." There is practically room for the head of one observer to occupy the place of vantage and to obtain a *fairly satisfactory view. But apart* from such disadvantages as the Laocoon-like contortions often necessary on the part of the laryngoscopist and the more or less confused crowding, due to want of space, on the part of the observers, the method is slow, limited of [illegible] and the proper demonstration of [illegible] within the larynx is quite out of [illegible] fessor Meyer of Berlin has been instrumental in changing all this and he has introduced a method which will, I believe, put the subject of laryngoscopy on a new footing and will render some service to the teaching of laryngology. I have had the opportunity of making a number of experiments with an apparatus constructed (with some modifications) from the model kindly shown me at Berlin by Professor Meyer and the results of these observations have been as follows It was found possible to show an image of the larynx, practically identical in every respect with that seen by the person examining the larynx, to as many as six observers at one time, the latter being situated at convenient distances from the patient, from the examiner, and from each other (Fig. 1). Also, intralaryngeal operations could be as clearly seen by the observers as by the examiner. The images were conveyed to the observers' vision by means of reflections on two circular plane mirrors, placed one on either side of the illuminating apparatus (Figs. 2 and 3). An observer situated at a distance of six or eight feet from the mirrors obtained as good an impression of the laryngeal image as a person situated close to the reflecting surfaces.

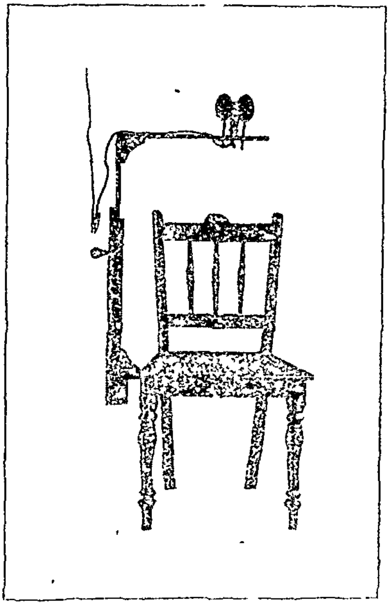
In the case of clinical meetings it has been found practicable to demonstrate laryngeal cases to about 130 observers in 20 minutes—two, three, *or more observers* examining at one time. In the experiments noted above most of the anatomical regions of the larynx could be demonstrated to the six (placed) observers by means of a laryngeal probe which was introduced, thus proving a method of teaching the topography of the larynx which had previously been possible only on specimens removed from the body. From a mechanical point of view the original apparatus

FIG. 1.



Six persons watching an intralaryngeal manipulation The mirrors into which they are looking, and also the patient, are *hidden, owing to the position of the examiner in the plate.*

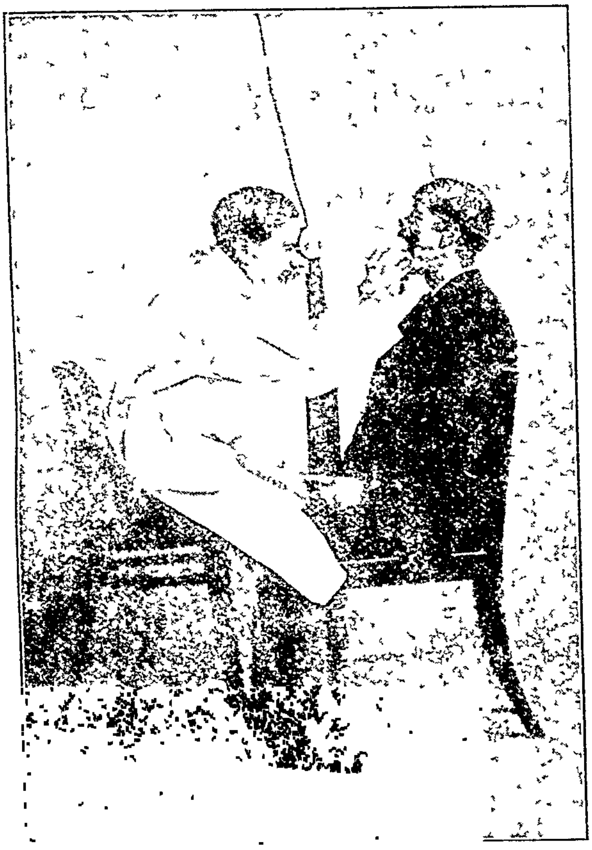
FIG 2.



Professor Meyer's original apparatus The chair is for the patient On the horizontal bar are the lamp with its electrical connexion and the two demonstrating mirrors placed at the best angle to catch the laryngeal image. The backs of the mirrors only are seen; the observers stand at the sides (*Vide Fig. 1.*)

(Fig. 2) can be briefly described as follows. There is, in the first place, a strong straight-backed wooden chair and on the right side of the seat is affixed a vertical arm. This arm is hollowed out to receive a smaller vertical arm and to this, in its turn, is attached at right angles a flat horizontal piece of wood. On that part of the horizontal piece which is nearly opposite the middle of the back of the chair (more correctly, facing the patient's mouth when he is seated in position) the laryngoscopic portion of the apparatus is placed (Fig. 2). The last-named part of the machine consists of a small electric lamp and two circular mirrors, each of the latter being three inches in diameter. Clear, unimpeded images of the larynx, or reproductions of any intralaryngeal operations which may be in progress, are reflected upon these mirrors. The examiner or operator looks through an opening in the sleeve of the electric lamp and thus gets a view of the larynx, as in the ordinary manner, except that he is only able to use one eye at a time. The inconvenience caused by this is almost negligible. The small modifications which I have thought useful are the construction of a detachable apparatus in which the essential laryngoscopic portion can be affixed to any laryngeal lamp-holder or upright, thus rendering the machine more portable and convenient and also considerably reducing its cost. Also, I am producing an apparatus by which four laryngeal cases can be shown (if necessary in rapid succession) to a number of observers simultaneously. The apparatus has been shown to the Laryngological Society of London and at other meetings and it is, I understand, being adopted at a number of teaching hospitals. Finally, the method is not proposed to supplant, for the student, the personal examination of the larynx but rather to stimulate his interest in the subject and to supplement his practical studies. The apparatus is made (in England) by Messrs. Armstrong and Brother, opticians, Deansgate, Manchester.

FIG 3.



Showing the method of examination. The light is thrown into the patient's mouth and the laryngeal image is projected from the laryngoscopic mirror on to two mirrors, one of which is seen close to the examiner's right eye. The faint impression of the larynx, which can be seen in the plate, is clear and well illuminated in the actual apparatus.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON FIBRO-MYOMA OF THE BULBAR CONJUNCTIVA.

BY KENNETH SCOTT, M.D., F.R.C.S. EDIN.,
CONSULTING OPHTHALMIC SURGEON, ST. MARY'S CHILDREN'S HOSPITAL, E ;
FORMERLY PROFESSOR OF OPHTHALMOLOGY AND OPHTHALMIC
SURGEON, KASR EL-AÏNI HOSPITAL, CAIRO, EGYPT.

THE occurrence of a fibro-myoma in this position is unusual and receives only slight passing mention in ophthalmic writings. This instance is perhaps worthy of note as the situation of the tumour involved the possibility of dangerous extension which would not only have interfered with vision but might have completely destroyed the utility of the eye, besides the ulterior risk of serious consequences connected with the fact of its very rapid and active recurrence. The growth unfortunately occurred in a medical colleague and he, probably quite correctly, associates the incidence of the tumour with an accident which happened to him while engaged in his professional duties. When he was breaking a tube of vaccine at a patient's house on August 12th of last year, a small piece of the glass flew up, struck against his right eye, and remained lodged there; it gave rise to much pain at the time and was only removed with difficulty and after considerable effort on the part of those in the house. He gave the incident no further thought until a month later, in September, when he noticed a small point of redness at the site of the recent injury in his right eye, on the sclera close to the inner edge of the cornea. This slowly increased in size and at the same time became thickened, but was not associated with pain, discomfort, or any other inflammatory symptom. There was never any question about the possibility of this being a modified form of vaccine pustule, as the lapse of time did not correspond, nor did it bear the least resemblance to such an inflammation.

The patient at once sought medical advice and used the various applications prescribed, but without producing any alleviation. The local condition soon became much aggravated, the growth increasing both in area and thickness very rapidly, so that on Oct. 12th, two months after receiving the injury, he obtained the able services of one of his friends, a surgeon, to remove the growth; this was skilfully performed with scissors and the small tumour was removed from the surface of the eyeball as completely as possible. When I had occasion to see the eye some days after this operation the wound had healed and there was only a slight redness present, limited to a portion of the sclera on the inner aspect of the globe opposite the palpebral fissure; there was no trace apparent of any extraneous morbid tissue remaining on the eye. The patient felt no local sense of irritation, there was no lacrymation, and only some tenderness of the eye on exposure to wind or to a draught of cold air.

On Nov. 28th, 47 days after the previous operation, I was consulted on account of the sudden reappearance of the growth and found that on the same site—viz., over the inner aspect of the sclera, close to the margin of the cornea and opposite the palpebral fissure, there was a very considerable accumulation of new solid tissue, upon, and closely connected with, the subjacent scleral layer; this surrounded, but avoided covering, the area occupied by the former tumour, thus giving the appearance of there being a wide depression in its centre. The growth measured four millimetres horizontally, three millimetres in vertical diameter, and was approximately one millimetre in thickness; it was of a brownish red colour and was semi-transparent; its surface was polished and its margin was distinct and clearly defined; there was entire absence of any sign of inflammation accompanying it. Each day it showed markedly rapid increase both in size and thickness, so that on Nov. 30th I was compelled to remove it entirely.

My first incision was made in the normal conjunctiva surrounding the tumour and then by very careful and complete dissection I excised from this marked-out area all the tissue lying superficially to the sclera. The surface thus exposed on the globe of the eye was a comparatively large one, but it healed gradually and satisfactorily and became completely covered with new epithelium without the formation of any cicatricial contraction. On Dec. 16th, 16 days later, the eye was quiet and the bandage and dressings were left off. Three days afterwards, when I was examining the eyes minutely by oblique illumination, I for the first time saw on the margin of the upper eyelid of the right eye (the eye which had been affected) a delicate fine eyelash which was inverted and rubbed against the surface of the globe, almost exactly at the point formerly occupied by the tumour. The eyelash was epilated and has not made any further appearance. Whether this had existed previously and taken part in the causation of the tumour or in its recurrence are questions which must remain undecided. The offending eyelash was an exceedingly fine one and could only be seen when examined through a lens of high magnifying power.

A careful histological examination of the recurrent growth was made after its removal and the following report was obtained: "After fixation in alcohol sections were made, placed in carbolic thionin, and stained. Result of examination.—Fibro-myoma. The cells are elongated, with rod-shaped rectangular nuclei, filling all the stroma which is fine, ribbon-like, and very crowded. At the periphery there are some vessels containing blood and some groups of microbes (probably ulceration)."

I understand that a similar result was yielded by microscopical examination of the tumour which was originally removed. Since the removal of the bandage and dressings over the eye no application or local medication has been employed, and the eye presents no indication, except on most minute and careful observation, of its recent condition and there is every reason to believe that permanent relief has now been obtained.

Manchester-square, W.

NOTE ON A CASE OF SO-CALLED "SPONTANEOUS FRACTURE" OF THE FEMUR FROM SECONDARY MALIGNANT DISEASE WITH SUBSEQUENT FIRM BONY UNION.

BY T. MORRELL THOMAS, M.D., M.S. LOND., F.R.C.S. ENG.,
HONORARY SURGEON TO THE NEWPORT AND MONMOUTHSHIRE HOSPITAL;
AND
B. G. FIDDIAN, M.B., B.S. LOND.,
RESIDENT MEDICAL OFFICER, NEWPORT AND MONMOUTHSHIRE HOSPITAL.

WE record the following case on account of its extreme rarity. According to Mr. S. Boyd, in his article on fractures in Treves's "System of Surgery," there are only some four or five on record. The patient, a married woman, aged 47 years, had her left breast removed for scirrhus 14 months prior to the date of fracture. The scirrhus was one of rapid growth, was fairly advanced, fixed to the pectoralis major, and there was palpable gland implication. She had had increasing weakness of both legs (? due to advancing cachexia) for six months prior to fracture and for the same length of time had "rheumatic" pains in both thighs. As these pains were more definitely localised over the future site of fracture it seems possible that they were due to implication of nerve fibrils in the growth. On Dec. 6th, 1902, while the patient was in the act of stooping to pick something up off the floor the left thigh suddenly snapped. She was admitted to the Newport and Monmouthshire Hospital two days after the accident and remained there till she died. On admission she was found to have sustained a fracture of the left femur at the junction of the upper and middle thirds. The limb was put up on a McIntyre splint. Thinking an ununited fracture was inevitable no extension was applied to the limb; we thought it would give her needless pain, so the limb was merely allowed to rest on the splint, being frequently taken down to guard against splint sores. Not much attention was paid to the condition at the site of fracture for the reason mentioned above. On Jan. 26th, 1903, however, seven weeks after the accident, an examination of the part showed that union had taken place. There was at this time a recurrence at the site of the removal of the breast as well as a mass in the liver. The patient got steadily weaker and died from secondary malignant disease on Feb. 15th.

Necropsy.—The site of fracture was cut down on and the upper half or so of the femur was removed *en bloc*. Such firm union of the fragments was found that they could not be torn apart even on the exertion of considerable manual force. A mass of cancerous growth was found wrapping the upper third of the femur loosely round and eroding it at the site of fracture—i.e., the upper end of the lower fragment and lower end of the upper—but the rest of the femur was uneroded. The conjoined mass of callus and malignant tissue cut like a scirrhus but with a gritty sensation at parts. It apparently extended from a chain of malignant glands which passed down from behind Poupart's ligament and seemed to have acquired an attachment to the periosteum. There was distinct overlapping of the fragments and to this union seems to have been due, for by this means unimplicated portions of periosteum were brought into apposition, not the diseased extremities of the fragments. A paring was taken from the mass in the neighbourhood of the end of one of the fragments and sent to the Clinical Research Association for microscopical examination. The report was as follows: "The tissues consist of periosteum and young bone with some adjacent fat and cellular tissue. They are all thickly infiltrated with narrow lines of scirrhus carcinoma."—Occurring as this case did subsequently to removal of a rapidly growing scirrhus, the result being firm union of the fragments and the condition of overlapping suggesting a possible explanation of departure from the sequence of events which is usual in such cases, we have thought it right that the case should be published.

NOTE ON A CASE OF TRANSPOSITION OF THE VISCERA.

BY EDWARD LIDDON, M.D. EDIN.,
CONSULTING PHYSICIAN TO THE TAUNTON AND SOMERSET HOSPITAL.

THE interesting case reported by Dr. William Hartland in THE LANCET of April 9th, p. 1017, reminds me of a very similar instance that came under my notice some years since when holding the appointment of honorary physician to the Taunton and Somerset Hospital.

A young man, aged 19 years, was admitted with pneumonia of the left base, and on examination it was discovered that all the viscera were transposed, the heart and spleen to the right, whilst the liver lay beneath the left ribs. He was a source of much interest to myself and to all my colleagues whilst he remained in the hospital. He made a good recovery from his illness and went into service near Brighton and for some years continued in good health. He had never been robust and always carried a "high colour," but until his attack of pneumonia he had suffered from no serious illness. His father died from some form of heart trouble; his brother, who had been a groom in my stable, was healthy and possessed no malformation. It was from him that I heard of my hospital patient's well-doing for some years after he left this neighbourhood.

Taunton.

CENTENARY OF THE RUSSIAN MEDICAL COUNCIL.—On April 22nd the Russian Medical Council completed its 100th year dating from its first session. It was founded on Dec. 31st, 1803, by order of the Minister of the Interior, Count Kotchubye, and was formally opened on April 9th, 1804. At the first gathering of the Council the Sovereign order for its constitution was read and a committee of five members was chosen to draw up the rules, duties, and prerogatives of the Council. It is proposed to celebrate its first centenary in a special manner on April 9th, 1905.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM.—The committee of management announces that the annual meeting will be held at the New Hospital, 4, Maida vale (near the end of St. John's Wood-road), at 4.30 P.M., on Thursday, May 5th, at which hour Mr. Charles Drummond, the treasurer, will take the chair. The annual report and financial statement for the year 1903 will be presented. After the meeting the New Hospital, now in full work, will be open for the inspection of those who attend this meeting.

CENTRAL LONDON OPHTHALMIC HOSPITAL.

OPTIC NEURITIS, OCULAR PARALYSIS, AND ABSENCE OF THE KNEE JERKS IN A CASE OF CHLOROSIS.

(Under the care of Mr. ERNEST CLARKE and Dr. C. O. HAWTHORNE.)

THE essential facts of the case here recorded can be stated in a few words. The patient, an unmarried woman, aged 22 years, was first seen by Mr. Clarke and Dr. Hawthorne at the Central London Ophthalmic Hospital on Oct. 27th, 1903. Her appearance and recent history were such as are common in cases of chlorosis and she was undoubtedly the subject of that disease in a moderately severe degree. In addition, however, to breathlessness and other familiar symptoms she complained of double vision and some failure of sight. These were of recent development (seven days) and their appearance had been preceded by severe headaches extending over a period of from three to four weeks. For the diplopia there was a very manifest cause in the shape of a paralysis of the left external rectus muscle. Similarly the defective vision (right $\frac{6}{18}$ left $\frac{6}{12}$) was associated with appreciable changes in each fundus oculi. These included considerable swelling (right + 4 D., left + 5 D.) of the optic discs with a few attendant hæmorrhages, a distended and tortuous condition of the veins and some evidences of retinitis, the last mentioned being specially marked in the right fundus. For the rest physical examination was entirely negative save in one respect—namely, complete absence of the knee-jerks. The personal history included an attack of scarlet fever four years ago but no other serious illness; the menses did not appear until the patient was 19 years old and had only been repeated in the form of a scanty discharge on three or four occasions. There was no reason whatever to suspect the presence of syphilis. The completion of the clinical record may be summarised in the statement that under rest in bed and full doses of iron the patient made a satisfactory recovery, though even as late as Feb. 17th, 1904, when she left the hospital, the right macular region showed some evidences of retinal disturbance and the vision with this eye was only $\frac{6}{12}$; the left fundus was normal to the ophthalmoscope and the vision $\frac{6}{5}$, there being in each eye less than 0·5 dioptre of hypermetropia. The first evidence of the success of the treatment was the relief of the headache. This ceased to be a source of complaint about seven days after admission. Some three weeks later the left external rectus muscle appeared entirely to have regained its power. The subsidence of the swelling of the optic discs was a very gradual process and was not complete until the end of January. Even then the knee-jerks remained absent and it was only in the first week of February, when the general condition of the patient had reached a high level, that their restoration was noted.

Remarks by MR. CLARKE *and* DR. HAWTHORNE.—The problem the foregoing clinical facts offer for solution is this: What is the probable relationship between the state of chlorosis on the one hand and a neuro-retinitis, an ocular paralysis, and a loss of the knee-jerks on the other? Regarding the absence of the knee-jerks it may be well to state that every care was taken to make the observation an exact and accurate one. The tests were applied with all the recognised precautions, they were repeated on many occasions during a period of three months, and the result was several times confirmed by independent observers. Whatever be the explanation the fact must be accepted as entirely beyond question.

Now of the three conditions named above, one of them, optic neuritis or neuro-retinitis, has for some time been admitted as a complication in a certain small proportion of the patients who come under observation as the subjects of chlorosis. The fact has attracted the attention of several observers but no one has succeeded in advancing an explanation generally accepted as adequate. In 1902 one of the present writers[1] recorded a case in which chlorosis was associated not only with double optic neuritis but also with an ocular paralysis (right external rectus), and some few other examples of a similar combination have been reported. These facts, with other considerations duly set forth at the time, suggested, it was urged, that a probable explanation of the optic neuritis occasionally occurring in chlorosis may be found in a thrombosis of the intracranial veins or sinuses.

The argument, so far as the individual case was concerned, was presented on the following lines: the simultaneous occurrence of the optic neuritis and the sixth nerve paralysis suggests a common causation; the nature of the two events makes it difficult to imagine any single cause capable of producing them other than an intracranial lesion; an intracranial thrombosis may certainly produce them; intracranial thrombosis is a recognised possibility in chlorosis; the patient is the subject of chlorosis; therefore it may be concluded with a considerable measure of confidence that an intracranial thrombosis is the cause both of the optic neuritis and the sixth nerve paralysis. And this position, it was suggested, supported the view that when optic neuritis occurs as the sole unusual event in a case of chlorosis intracranial thrombosis may be accepted as the probable cause. The case now recorded may be held to strengthen this theory so far at least as it is a further illustration of the possibility that some event or events included among the occasional developments of chlorosis may produce both a double optic neuritis and an ocular paralysis. But the facts of the case go beyond this. They include a prolonged absence followed by a complete restoration of the knee-jerks. Hence it becomes necessary to consider whether the further fact suggests or compels any modification of the view that intracranial thrombosis is the cause of the optic neuritis seen at times in chlorotic women. Of course, there is no actual proof that the three events—optic neuritis, sixth nerve paralysis, and absence of the knee-jerks—are results of one and the same cause. But they offer themselves as phenomena occurring at or about the same date, each is a quite unusual event in the course of chlorosis, and all of them signify some disturbance in the nervous apparatus. Hence, unless good reason to the contrary can be shown it seems necessary to regard them, at least in all probability, as events of an identical order and dependent upon a common cause. Now it may at once be allowed that it is very difficult to believe that an intracranial thrombosis producing no more serious objective disturbance than optic neuritis and a sixth nerve paralysis can be held responsible for absence of the knee-jerks. Tumours of certain parts of the brain and also basal meningitis may, it is true, be quoted as intracranial lesions which have been known to cause such a result, but it would need some courage to advance a limited intracranial thrombosis as equal to this effect. It must, therefore, be admitted that absence of the knee-jerks in a case of chlorosis attended with double optic neuritis and an ocular paralysis does not add force to the suggestion that the neuritis and the paralysis are due to an intracranial thrombosis. If all the three conditions are to be referred to a common cause little can be said in support of the hypothesis that intracranial thrombosis is that cause.

Another reading of the development of optic neuritis in chlorosis is that it is a consequence of the abnormal state of the blood and the question may therefore be asked whether the facts of the present case can be better brought into harmony with this theory rather than with the doctrine of intracranial thrombosis. It is certain that an ocular paralysis and absence of the knee-jerks observed in conditions known to produce degenerative nerve changes as the result of an altered quality of the blood—say, for example, diabetes or diphtheria—would be regarded without hesitation as consequences of a common cause—namely, peripheral neuritis. Equally there can be no difficulty in admitting that neuro-retinitis may be produced by a changed character of the blood supply. Examples of this are familiar in chronic interstitial nephritis, secondary syphilis, and other diseases. Again, such experiences as the association of optic neuritis with herpes and with lead paralysis show that one and the same poison may attack both the optic nerve and other peripheral nerves of less specialised function.

---

[1] Hawthorne: Brit. Med. Jour., Feb. 8th, 1902.

The occasional development of an ocular paralysis with herpes of the face and the occurrence of retinitis, ocular paralysis, and loss of the knee-jerks in diabetes may be used as further illustrations of the possible manifestation of changes in the peripheral nervous apparatus capable of being produced by an altered quality of the blood. Such facts may all be utilised to strengthen the argument that in the present case the neuro-retinitis, the ocular paralysis, and the loss of the knee-jerks are all expressions of effects produced on peripheral nerve structures by the abnormal blood quality which exists in chlorosis. And the joint association of these three events in one and the same case may reasonably be urged in support of the view that it is in an abnormal state of the blood and not in intracranial thrombosis than an explanation of the optic neuritis of chlorosis is to be found.

In brief, it may be recognised that the facts of the case now under discussion, at least at first sight, adapt themselves to the theory just stated more readily than to the hypothesis of intracranial thrombosis. Is it therefore necessary to abandon the latter event as the probable cause of optic neuritis in chlorosis? Before doing so it may be well to consider what may be said in arrest of judgment. And at the outset it is proper to remark that the facts now presented are illustrated only by a single case. Neither loss of the knee-jerks nor any other symptom that may be regarded as a manifestation of peripheral neuritis is included among the phenomena of chlorosis, unless it be that various neuralgic pains may be so interpreted. Now, considering how sensitive is the nervous arc upon the integrity of which the knee-jerk depends to the action of various poisons which have a prejudicial influence on the peripheral nervous apparatus, it is indeed remarkable, if chlorosis is capable of exercising such an influence, that evidences of peripheral nerve changes are not, at least occasionally, noted among the facts of that disease and this more especially when it is remembered that examples of the disease are constant and universal. Upon such a view it would have been expected that peripheral nerve disturbances would have been common and that loss of the knee-jerks would have been a frequent index of their existence. On the other hand, absence of the knee-jerks, though probably always pathological, is occasionally noted in circumstances which fail to supply any explanation of the condition. Caution is therefore necessary before adopting the assumption that such absence in the present instance is necessarily the expression of peripheral nerve changes due to an abnormal quality of the blood. The suggestion of a satisfactory alternative is not easy, but the long array of negative observations is in the circumstances a warning against a too ready acceptance of a somewhat inviting conclusion.

Again, it must be remembered that there exists a considerable body of direct evidence that optic neuritis with [illegible] curring in chlorotic [illegible] intracranial throm- [illegible] st-mortem examinations and in part by cases in which together with optic neuritis there was thrombus formation in the veins of the lower limbs or elsewhere. Detailed reference to these will be found in the paper already quoted and with these other arguments directed towards the same end. It would appear doubtful policy to abandon the significance of all this under the temptation offered by one fact in the history of a single case, and that fact perhaps not quite capable of an unambiguous interpretation.

Further it may be fairly remarked that the ophthalmoscopic aspects of the case offer a strong suggestion of the existence of some gross intracranial lesion. Such a considerable swelling of the optic disc as will justify the application of the term "choked disc" is not a condition commonly seen among the fundus changes produced by an altered quality of the blood. On the other hand this fact is a familiar note of the presence of an intracranial tumour and with it there may exist, from the same cause, evidences of widespread retinal disturbance. The point, it is true, is one of degree and not of kind, for blood changes and intracranial lesions alike must each be admitted as events competent to produce both swelling of the optic discs and generalised retinitis. Yet it is not without significance to observe that the ophthalmoscopic picture displayed in this case of chlorosis—and the statement is equally true of other similar cases—was one that conveyed to the mind a conviction of the presence of an intracranial lesion rather than an impression of inflammatory changes produced by an abnormal condition of the blood-supply. At the same time it is necessary to admit that the case has amongst its phenomena at least one which inclines the balance rather against than for the theory of intracranial thrombosis.

It may, of course, be said that on any view one case carries but little weight. But it is essential to deal with all the facts in an endeavour to frame a comprehensive theory. And facts of the order here presented would appear to be of such rare occurrence that no one observer has the opportunity to accumulate from his own experience a collection adequate to sustain an authoritative pronouncement. It is only by contributions from numerous sources that a body of material sufficient for this purpose can be secured. Hence the necessity for all observers to record their individual experiences. It is in recognition of this claim that we report the present case. Of all the problems associated with optic neuritis its occurrence in chlorosis is surely one of the most interesting, and as post-mortem evidences in such cases can rarely be available it is the more desirable to multiply so far as possible the number of exact clinical observations.

ROYAL DEVON AND EXETER HOSPITAL.

A CASE OF INTRACRANIAL HÆMATOMA.

(*Under the care of Mr. J. DELPRATT HARRIS.*)

FOR the notes of the case we are indebted to Dr. W. Gordon and Mr. Harris.

On August 17th, 1903, a labouring man, aged 62 years, was taken to the Royal Devon and Exeter Hospital with the following history. On June 21st he was knocked down and rendered insensible in a stone quarry by a stone falling on the top of his head. He was stunned for a short time and was able to walk home. For the first fortnight he only complained of bruises in different parts of his back and loss of sleep. This latter was the only nerve symptom which so far had manifested itself. He then began to complain of sciatic pains on the right side with partial loss of power in the right leg with exaggeration of the knee-jerk. At the end of two weeks this pain passed away and the power of the limb so far recovered that he was able to walk out. Loss of power on the left side now gradually set in until he arrived at his condition on admission. There had never been any signs of paralysis of the left side prior to this. There were no scalp wounds or other wounds, only bruises. There were no mental symptoms until a month after the accident, about the same time that the paralysis began to appear on the left side. The stone was said to be about seven pounds in weight, probably flat, falling from no great height. He himself fell but only his own height on loose quarry rubble. During the fortnight he was in complete possession of his faculties he repeatedly complained of pain and bruises all over his body, principally on the back of his neck but also in the lumbar region, the left arm, and the wrist. Shortly after the accident his eyelids showed much ecchymosis but neither his nose nor ears bled at all. On admission his condition was as follows. He was more or less imbecile, nervous and suspicious, and could give no proper account of himself; he was talkative and restless. No signs of injury were seen in the scalp or the face. There were no tender points. The pupils were unequal, dilated, and moved slowly to light reflex. The tongue was evenly protruded. The thorax, the lungs, and the heart were all normal. The abdomen was somewhat distended and all the abdominal reflexes were present. The left arm was wasted, with contracture to an angle of about 70°, it could be nearly straightened but with much pain. The bicipital reflex was marked. The elbow and the wrist reflex were present. The fingers were strongly contracted into the palm of the hand. Both legs were somewhat wasted, the right especially, the skin on this side being atrophied and the heel somewhat red. Both limbs were very rigid, the left the more so. The left was in a condition of spastic rigidity with adduction and the knee jerk on this side was excessive. Ankle clonus was not present. There was incontinence of urine. The pulse was slow and regular; the temperature fluctuated between 97° and 98° F. Great pains were taken to collect reliable information as to the accident and its immediate result. The case was carefully watched also, the immediate point of interest being whether any gross lesion existed in the spinal canal or whether intracranial mischief alone could account for all the symptoms. Efforts were made to observe the optic discs, but owing to the ceaseless restlessness and talkativeness fleeting glimpses were all that could be obtained. The apparent outer margin of the left disc seemed blurred but the disc otherwise was normal, whilst the right disc did not betray any marked abnormality.

On Sept. 5th the patient was trephined over the right motor area. The scalp bled more freely than usual; the bone was unusually soft. The dura mater was found to be yellow and opaque. Its pulsation was diminished. On incising it the arachnoid bulged up, appearing dark and somewhat greenish. On incising this deep claret-coloured clot protruded, evidently under pressure, and on prolonging the arachnoid incision a quantity of altered blood clot and serum poured out per saltum. Certainly not less than four ounces must have thus come away, probably more. A drainage tube was inserted and the wound was closed, the tube passing through the flap. The cavity of the hæmatoma as gauged with a probe was not smaller than an average hen's egg; it was of irregular shape, with its long axis antero-posterior. This, which was more or less centrally over the Rolandic fissure, therefore involved all the upper motor centres and considerably trenched on the anterior frontal lobes. Prolongation of the cyst extended immediately downwards towards the base.

The immediate result of the operation was most definite, for the left arm and left leg became quite flaccid on the following day, the 6th. The pupils were dilated but contractile to a lighted match. There was no improvement in intellect. On the 7th the patient could move the fingers of the left hand slightly and raise the left leg from the bed. He asked for the urinal on this day. On the 11th it was noted that rigidity of the arm and leg had returned. The pupils reacted still but he passed urine in bed again. On the 12th, finding his improvement stationary and some of the symptoms less satisfactory, it was decided to reopen the wound and to see whether any fresh hæmorrhage had occurred, and failing that to scoop out the layers of fibrin which might be the cause of the continued compression, if such could be done without setting up fresh hæmorrhage. The wound being reopened and the clots around the opening in the dura mater removed, the bone was extensively "nibbled" away, exposing a surface of dura mater not less than two inches by two inches. The dura mater was then quite freely opened and the arachnoid also, the clots were turned out, mostly by the finger, aided by a tepid douche of sterilised water. The clots turned out were about from one and a half to two ounces in bulk. The brain was collapsed, opaque, whitish grey in colour, and it was noticed that it did not expand or pulsate; an exploring trocar was therefore introduced about half an inch to search the brain for abscess or hæmatoma, but none was found. The dura mater was carefully stitched. Iodoform gauze was lightly introduced to arrest any capillary hæmorrhage in the walls of the cyst and the wound was closed.

On Sept. 17th, the fifth day after the second operation, the notes state that up to that day the spastic condition of the left arm and leg had been lessening and the over-sensitive reflexes were almost abolished. The patient was very talkative (nonsense) and passed urine and fæces in bed. The iodoform drain was shortened on alternate days and was draining well. He had taken his food well—fluids and milk pudding. Choroiditis was clearly seen in the right fundus; the left disc was reddish and blurred on the apparent outer side, but was pale and grey on the inner. On the evening of the 16th he had an epileptiform attack lasting three minutes affecting the right side of the face markedly, clonic spasm in both arms and both legs, the body being turned towards the left. Coma came on and recovery soon followed. Up to this date his mental condition was very unsatisfactory, violent delirium requiring restraint, with great talkativeness, often of a quaint sort with delusions, being the rule. About five hours after this "fit" his mental condition improved and he asked for the bedpan and also the urinal. After this he moved his left leg and arm voluntarily and by the 19th it was noted that whereas he could be restrained by having the right side only tied down it now became necessary to tie down both arms as he was so very restless On the 24th the paralysis was completely gone. His mental condition had improved on the whole but he was still subject to fits of excitement requiring restraint. They were getting less, however, and a short conversation was now maintained correctly, but if prolonged his attention wandered and he talked nonsense. The pupils now reacted to light and his knee-jerks were normal. The wound was looked at and found to be healed with the exception of two small surface wounds. On Oct. 13th he was wonderfully better; the mind was much clearer; once or twice a day he talked nonsense for a few minutes. There was no defect of speech and he could see and hear well. He walked well with no limp or staggering. The effect of each operation on the temperature was marked. Prior to the operation it seldom touched normal as related before; after the first operation it touched normal daily although it might be 97° a portion of the day. On the day following the second operation it touched 101°, coming down to normal on the fourth day, going below normal on the fifth, and gradually ascending to normal during the third and fourth week where it remained, but having a tendency to subnormal temperature of a morning. On the 25th his mental condition was quite sound and he left the hospital on Nov. 19th absolutely well, though a little pulled down by all he had gone through.

In THE LANCET of August 29th, 1903, p. 597, there was reported an interesting and unusual case of intracranial hæmatoma. The above case occurred in my hospital practice at the time of the publication of the case alluded to. It would, I think, be instructive to compare the two cases. There are several points of interest in the case, both medical and surgical, and first the amount of credence to be placed on the history. In the end it became evident that the patient's history of the accident was, in the main, correct. The extreme slowness with which the symptoms came on is another feature and clearly marks the difference between compression of the brain from middle meningeal hæmorrhage and subarachnoid. Doubtless the excessive slowness with which the blood was poured out from the smaller vessel was the cause; yet that a fortnight should elapse before any serious symptoms occurred is certainly surprising. That the earliest symptoms should have been pain in the right leg was misleading and led some of us to suspect a second lesion in the cord and that possibly the bladder trouble was referable to it also. If this were the case it must have been hæmorrhagic in character for the patient repeatedly denied that he felt any difference in the two legs on his recovery. The extreme pain which he had in the back of his neck received careful consideration, but it was probably due to osteitis set up by the violent blow. That the arm was in a condition of contracture as well as the leg was an important guide and helped to place the lesion high up in the cerebrospinal system. There was no history of facial paralysis and so the higher portion of the pons was excluded from any share of compression. It was felt that too much importance must not be laid on the mental symptoms as aids to localisation as communicated pressure may cause such symptoms. Nevertheless, taken in conjunction with his motor symptoms, it was felt that should the motor area be the seat of a clot or hæmatoma any extension forwards would be likely to embarrass the functions of the frontal lobe. These considerations and the fact that his then condition was pitiable in the extreme led one to trephine first with a view to examine the cord later by laminectomy if sufficient was not found by trephining the skull. That the first operation was not followed by permanent improvement was clearly due to the collapsed brain not having the power to expand and to press the cyst wall flat, for the latter was thick and hard from partially laminated clot. Nevertheless, the operation being done in two sittings much diminished the risk of fresh hæmorrhage refilling the cyst. A point of some further interest occurs in the rapidity with which the muscles of the arm and leg regained their normal tone and contracture ceased—less than 24 hours—as compared with the couple of months required for the mental symptoms finally to disappear. The beneficial effect of the epileptic attack must, I think, be referred to the expanding brain on regaining its normal blood supply becoming "charged" for a nerve explosion and its regaining its normal blood-supply was the cause of the improvement rather than the fit. The notes stating that during the fit his body was rotated somewhat towards the left and the right side of the face was convulsed are important as showing that the muscles on the right side were stronger than those on the left, the brain being irritated by a central lesion which had injured the motor centres on the right side. It is interesting to observe that the epilepsy was not so complete on the right side of the brain. No torn portion of brain could be found and from which artery the hæmorrhage came it is not possible to say. As an instance of the quaint humour of the patient's rambling talk I may relate that when he kept trying to get out of bed, being asked why, he said, "I got a job on Thursday. I must go to a funeral at 12 o'clock." Being told he had better remain, he said, "Well, but I must be there, they can't do it without me Tell'ee the truth, 'tis my own funeral and that's a job they tell me I can't get out of."

Remarks by Dr. GORDON.—The diagnosis in this case was one of some interest. The occurrence of a monoplegia on one side after the accident succeeded by a more alarming hemiplegia on the other side was curious, but in the chief difficulty lay the clue. The lesions were obviously not spinal in origin. They seemed certainly due to the same cause—viz., the blow from the stone. This had been inflicted fairly on the centre of the crown of the head, therefore over both leg centres and consequently over the parts most concerned in the subsequent palsies. If the first leg affected had been solely and temporarily affected one would have [illegible] amaged vessel. It therefore [illegible] attack of paralysis was due [illegible] ide. Again, as the result of the accident, it seemed scarcely conceivable that a tumour could so soon have developed, and that it had not developed was clear in the absence of the severe headache, sickness, and optic neuritis which a growth so rapid would almost certainly have produced. If an abscess had been set up these three signs might still be wanting, but here the absence of leucocytosis indicated that there was probably no abscess. Hæmorrhage remained as the probable diagnosis. The correctness of this diagnosis was verified at Mr. Harris's very successful operation. We were much indebted to Mr. R. Walker of Clovelly for most careful and important notes of the patient's early condition.

ABERYSTWYTH INFIRMARY AND CARDIGANSHIRE GENERAL HOSPITAL.

A CASE OF UNUSUAL FRACTURE OF THE CLAVICLE.

(Under the care of Mr. R. T. EDWARDS, house surgeon.)

THE patient, who was a young man, aged 18 years, met with an accident whilst at work on the railway. He was coupling two trucks and whilst doing so the engine was set in motion unknown to the patient, with the result that he was more or less crushed between the two buffers. After recovering from the shock produced he walked to the Aberystwyth Infirmary not because he suffered from the usual symptoms of fracture but merely to ascertain whether he had suffered any serious injury. Mr. Edwards watched the patient walking up to the hospital and could not detect the characteristic attitude generally assumed by patients suffering from the results which follow a fracture of the clavicle. Then on examination he failed to find any deformity in the neighbourhood of this bone except that its length was slightly shortened compared with that of its fellow on the opposite side. The usual clinical features present were conspicuous by their absence; that is, the elbow was not flexed, neither was it supported by the opposite hand—in fact, the patient could raise his arm above the level of his head without experiencing the slightest degree of pain. At this stage Dr. Abraham Thomas, the honorary surgeon to the hospital, arrived and he also failed to detect any signs which might go to prove, or even to suggest, a fracture of the clavicle. The youth was detained as an indoor patient and was put to bed in order that fomentations could be applied to some contusion that was present over the shoulder-joint. On the next morning Mr. Edwards discovered that there was a complete fracture through the middle third of the clavicle with the usual displacement, the sternal fragment being slightly drawn upwards by the sterno-cleido-mastoid muscle and the acromial part being depressed by the weight of the arm. The sternal fragment over-rode the acromial to the extent of about a quarter of an inch.

Remarks by Mr. EDWARDS.—Impacted fracture of the clavicle being one that is not commonly mentioned in ordinary text books on surgery I thought this case to be one well worth recording. In my opinion it appeared to be a case where the force had not been indirectly transmitted, as is usual, through the glenoid cavity to the scapula and thence by the coraco-clavicular ligaments to the clavicle, which force, being of a twisted character, would naturally have produced some displacement. Instead, I presume the impact in this case must have been direct on the acromio-clavicular joint and thereby the force being straight in its direction produced the impaction instead of the usual displacement. The unconsciousness naturally produced by sleep, and possibly the position adopted by the patient in bed, produced a relaxed state of the muscles and thus afforded an opportunity for the broken fragments to become manifestly displaced.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Economic Value of the Sanatorium Treatment for the Working Classes based upon After-histories.

A MEETING of this society was held on April 26th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. NOEL DEAN BARDSWELL and Mr. JOHN E. CHAPMAN communicated a paper on the Economic Value of the Sanatorium Treatment for the Working Classes based upon After-histories. They said that their paper dealt with the consideration of the life-histories of 28 consumptive patients who were treated in the Sheffield Royal Infirmary between June, 1899, and March, 1900. These patients were accommodated in two of the general wards of the infirmary specially reserved for the purpose and facilities were made for carrying out the main essentials of the sanatorium treatment—viz., a maximum amount of open air, an adequate diet, and regulated rest and exercise. The diet, which was a modification of a hospital convalescent diet, consisted of breakfast at 6.30 A.M. of porridge, bacon and eggs or fish, bread and butter, and half a pint of milk; half a pint of milk at 10 30 A M.; dinner at 12.30 P M. of meat and two vegetables, milk pudding and fruit, with half a pint of milk or beer; tea at 4 30 P M. of bread and butter or jam, and an egg, with half a pint of milk; supper at 7 P.M. was the same as at breakfast, with half a pint of milk; half a pint of milk was also allowed for each patient during the night. The cases admitted were quite unselected and the proportion of patients with a really good prognosis was very small. Of the 28 admissions 11, or 39 per cent., were clinically hopeless cases, and only 16, or 57 per cent., appeared to have a chance of being restored to a fair working capacity. In eight cases in which the disease had lasted six months two or three lobes of the lungs were involved; in eight cases in which the disease had lasted from six to 12 months three or four lobes of the lungs were affected; and in 12 cases in which the disease had lasted 12 months or more four or five lobes of the lungs were affected. In a table the cases were classified according to their clinical types, the classification being based upon Fowler's description of types of pulmonary tuberculosis. The patients with miliary, acute, caseating, and very advanced fibro-caseous disease, 39 per cent. in all, were not appreciably benefited by treatment, and satisfactory results were only obtained in the 57 per cent. who had either fairly recent active disease or chronic slowly progressive mischief of considerable duration. Of the 16 patients who belonged to one of these two classes nine were discharged restored to their full working capacity and seven were sufficiently improved to allow of their return to light work. The ultimate or economic results were then dealt with. A table was given showing the after histories of the 16 patients who returned to work, the statistics covering a period of four years subsequent to their leaving the infirmary, the basis of the classification being that of their various wage earning capacities during this period. In the course of four years, of the nine patients who were restored to their full working capacity three died, two were lost sight of during the third and fourth year respectively (their conditions when last heard of being in every way satisfactory), and the remaining four maintained their health and were *at full work throughout*. Four patients then, certainly, and possibly six, of the nine now under consideration had successfully withstood the strain of four years' work and judging from the condition of the two who were lost sight of it was probable that both of them might also still be in good health. The record of the seven patients who were only partially restored to health was less satisfactory, since the expiration of four years found only one of them alive, though up to the end of the third year three of them had remained well enough to do a certain amount of work. The proportion of permanent successes would doubtless have been greater had the social conditions returned to in several instances been satisfactory. The factors which had been chiefly instrumental in determining the ultimate results obtained were the conditions of the patients from the point of view of social economy—viz., the amount of income, financial obligations, and family and conditions at home and at work. The influence of occupation was next dealt with. Dr. Bardswell and Mr. Chapman said that the nature of the employment on which the arrested consumptive depended for his livelihood had such an important bearing upon his future that a decision as to the kind of work he should return to became one of paramount importance. But it was usually difficult for men to exchange injurious occupations for work of a satisfactory nature without incurring considerable financial loss. It was found that no less than 22 out of the 24 men admitted were dependent for their livelihood on occupations to which it would be undesirable for a case of arrested tuberculosis to return and this fact illustrated the great odds that the consumptive working man had to contend against in large cities. Of these 24 men, however, only 15 on their discharge actually resumed work, and of these no less than 12, or 80 per cent., managed to change their employment—a remarkably high proportion. Of the three men who returned to their original employments, two—viz., a cycle mechanic and a stone mason—quickly relapsed, although the former was on clinical grounds a very promising case. The satisfactory occupations were those of Telephone Company's labourer, steward of working man's club, tram conductor, rate collector, workhouse infirmary attendant, van driver, hall porter, and doing odd jobs in Australia. Commercial travelling and working on farms both proved failures, the work in each case entailing too much labour. In conclusion it was said (1) that general hospitals, even when situated in large cities, could do a great deal for their consumptive patients; (2) that the sanatorium treatment could be carried out with a considerable degree of success in institutions other than those especially constructed for the purpose; (3) that to obtain satisfactory economic results patients admitted should be rigorously selected, unmarried men with early disease who are both willing and likely to have the opportunity of returning to suitable employment having the best prognosis; and (4) however satisfactory the immediate results of treatment might be in the case of the working man the risk of subsequent relapse was very great unless his social status allowed of his living and working under at least fairly favourable conditions after discharge.

Dr. C. THEODORE WILLIAMS said that he thought that the results which Dr Bardswell and Mr. Chapman had obtained could not be considered as satisfactory. They had dealt with such a small number of patients that it was impossible to draw conclusions which could be considered of statistical value. He referred to the work of Dr. J. E. Pollock at the Brompton Hospital who had kept under observation some 3000 cases as out-patients and the percentage of those who did well and were able to continue at work was greater than in those observed by Dr. Bardswell and Mr. Chapman. He did not consider that gain in weight was necessarily any indication of the improvement of the patient. He was of opinion that it was of the greatest importance to find suitable occupation for patients after the disease had become arrested and advocated the formation of colonies for tuberculous patients

Dr. J. KINGSTON FOWLER, after criticising the classification of the cases, said that although the extent of the disease was a most marked factor in prognosis, yet he was more and more inclined to base his prognosis of a case on the temperament of the individual and not so much on the physical signs Both from the economic and philanthropic points of view it was essential to treat the cases early. The cases which did best were those with limited lesions and unmarried men with no one dependent on them. He did not agree with the last speaker that the results obtained were so very unsatisfactory when it was taken into consideration the unselected cases from which they were derived. As occupation he advocated nursery gardening and said that for two years after the arrest of the disease no more violent exertion than walking should be indulged in. He also advocated colonies for those cases with arrested disease.

Dr. F. RUFENACHT WALTERS said that the cases treated of in the paper were such that they required much longer treatment than they had received. He had seen many cases put on a considerable weight but with no real benefit to the patient. The proportion of early cases, even in the better classes which came for sanatorium treatment, was extremely small and, he should think, did not amount to more than 10 per cent.

Dr. T. GLOVER LYON referred to some 20 cases which he had treated as out-patients at a London hospital. He said that not one of these had recovered sufficiently to return to work. He considered that treatment of these patients in sanatoriums was unsatisfactory, since it frequently produced a moral deterioration which unfitted them for a return to work.

Dr. A. NEWSHOLME said that as medical officer of health he regarded the question from a somewhat different point of view. The young unmarried man without liabilities might, from the economic standpoint, be the case most suitable for treatment, but from the public point of view it was much more important that the wage-earner of the family should be carefully looked after since his life was of greater value to the community. He emphasised the importance of educating these patients in personal hygiene and said that he had often seen the wife and children infected with tubercle by a tuberculous father. The early diagnosis was of great importance and in every case of doubt the sputum should be submitted to an early examination.

Dr. P. HORTON-SMITH said that if good results were to be obtained the cases must be treated early. He suggested that the friendly societies should give full pay to the individual during the early stages of the disease, so as to relieve the patient from all anxiety and to enable him to be treated during the earliest stage of the disease, and in this way the best economic results would be obtained.

The PRESIDENT said that for prolonged treatment of phthisis the wards of a general hospital were quite unsuitable but they were of great value in the treatment of the acute phases of the disease. He thought that the early stages of the disease were more often seen at the general hospitals than at the special hospitals. Some patients applied there on the first manifestation of the disease and he advocated that a few beds should be reserved in each general hospital for the treatment and the careful examination of such cases, and that after a few weeks they should be sent to convalescent homes or sanatoriums. Physicians could only lay down general lines of treatment both in life and work and patients should be taught to live under similar conditions to those they had experienced in sanatoriums. He advocated the formation of colonies for the after-care of patients who had recovered, but only such patients should be sent there who had learnt how to live without being a danger to their fellow men. Although the cases in the later stage of the disease were of no economic value to the community yet they demanded our sympathy and consideration, and for the advanced cases special arrangements should be made where careful feeding and attention were possible without the routine of a sanatorium. The economic output should not be the only outlook of a hospital, and a hospital should not only treat early cases of phthisis but also advanced cases.

Dr. W. EWART was strongly of opinion that it was essential that cases of phthisis should be treated in the wards of a general hospital and not be sent at once to sanatoiums, since the patient was benefited, he was taught to look after himself and to avoid infecting others, and much was to be learnt from the daily observation and treatment of such cases.

Dr. G. NEWTON PITT said that although sanatoriums were beneficial it was necessary to have colonies where these patients could work. There was a great difficulty in obtaining suitable employment for partially cured patients. Patients having got used to open air could not work in confined space and the open-air life demanded more food. He suggested that the organisation of work might be arranged in part by the infirmaries and in part by the friendly societies and the parish councils. He said that he had seen great mental deterioration result from sanatorium treatment.

Dr. BARDSWELL replied.

MEDICAL SOCIETY OF LONDON.

Prevention and Early Treatment of Disease.—A Case of Perityphlitis simulating Malignant Disease.

A MEETING of this society was held on April 25th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Dr. W. J. TYSON (Folkestone) read a paper entitled "The Prevention and Early Treatment of Disease." He first referred to what had already taken place in the prevention or amelioration of diseases and mentioned ague, septic diseases, diphtheria, myxœdema, and typhus fever, but thought that this work was only an earnest of what was to follow. He then spoke of the future treatment of tuberculosis, cancer, and diseases of the intestinal tract, and referred to the question of milk-supply, saying he trusted that before many years had elapsed pure milk (which he defined as unboiled, unsterilised, and unadulterated milk) would be obtainable by every man, woman, and child, but this would never be effected until an official pronouncement had been made by the heads of the profession on the subject of milk reform. It was pointed out that the Education Act was sadly deficient. Although it provided for the religious and intellectual side of education the purely physical side had been almost completely neglected and no one competent to deal with, or to advise on, this subject had been elected as representing this aspect on the school boards. He suggested that every board throughout the country should [illegible] should be taken up in that order. Large sums of money were wasted in hospitals, infirmaries, dispensaries, and inebriate and other homes for the treatment of patients far advanced in various diseases. The treatment was begun, so to speak, at the wrong end. The physician of the future would be a far more important person than he was to-day, because when general principles of physiology and the laws of health became common knowledge the superstitious belief in futile remedies would cease and quackery would die a natural death. Then medicine would no longer be regarded as the art [illegible] or [illegible] abc[illegible] rightly belonged to him—namely, that of the most important functionary in an enlightened and progressive State.—Dr. G. C. STEELE PERKINS, referring to the subject of the prevention of appendicitis, adverted to the large quantity of frozen food consumed in London which he regarded as a potent cause of the condition. The boiling and sterilising of milk was a most important matter. Many of the processes deprived the milk of its nutriment.—Dr. W. EWART hoped that increased education would lead to the protection of the public. The work of the medical profession in the future must be preventive rather than curative. How to preserve the teeth was a most essential and important question.—The PRESIDENT referred to the difference which 300 years had made in the death-rate from ague in this country. In regard to septic diseases he could remember when he was a dresser two cases of strangulated hernia in which the patients died from septicæmia. The treatment of anæmia (one of the chief causes of gastric ulcer) should be very prolonged and oral sepsis also needed preventive treatment.

Dr. SEPTIMUS P. SUNDERLAND, in the absence of Mr. H J. CURTIS (now surgeon to the Memorial Hospital, Buluwayo), communicated a paper by them on a case of Perityphlitis simulating Malignant Disease which was completely relieved for 19 months by a lateral intestinal anastomosis, followed by acute abscess of the appendix, appendicectomy, and cure. The patient was a female, aged 36 years, who had had occasional pains and discomfort for several months in the right iliac fossa. She began to have constipation and vomiting and developed a tender swelling in the right iliac fossa and a high temperature. When she was admitted to the Royal Waterloo Hospital for Children and Women she had recently lost a stone in weight. The swelling was regarded as a perityphlitic abscess and the abdomen was opened by Mr. Curtis, a lump as large as a cricket ball being found in close connexion with the cæcum apparently involving the posterior wall of that structure. The appendix could not at that time be found. The lump was regarded as malignant. A lateral anastomosis of the ileum and ascending colon was made. 21 days later the abdomen was again opened with the hope of removing the mass but this was found impossible. 24 days afterwards the swelling, which had been gradually diminishing after the second operation, had almost entirely disappeared. Convalescence was slow but the patient resumed her work five months after leaving the hospital and continued in fair health for a period of 12 months. Pain and tenderness then came on again in the right iliac fossa and a lump as large as a bantam's egg appeared under the scar of the operation wound, with a rise of temperature. A third operation was performed by Mr. Curtis and the appendix was then found free and inflamed, surrounded by a tablespoonful of grey odourless pus, and was removed. The resulting sinus was subsequently excised at a fourth operation and the patient made a complete recovery. The case showed the difficulty which sometimes existed in determining whether a tumour, although exposed by abdominal incision, was malignant or not. Mr. Curtis, on considering the facts of the case, the delayed convalescence, and the subsequent history, now regarded the mass found at the first operation as being probably of tuberculous origin. Dr. Sunderland inclined to the belief that the original swelling was an inflammatory mass due to appendicitis, which disappeared without the formation of pus partly owing to the intestinal anastomosis and regarded the condition found at the second operation as the result of a recurrent attack of appendicitis. Dr. Sunderland regretted the absence of his colleague, Mr. Curtis, to whose careful surgical skill the case owed its favourable termination.—Dr. H. A. CALEY referred to a similar case of a man, aged 72 years, in whom the symptoms resembling [illegible] inflammatory. Great cauti[illegible] of such conditions.—M[illegible] cases, one of ovarian disease and one of cæcal disease, bearing on the question of diagnosis.—The PRESIDENT mentioned two cases presenting the symptoms of appendicitis which were found to depend on malignant disease.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 22nd, Dr. FREDERICK TAYLOR, the President, being in the chair.

Mr. F. J. STEWARD exhibited a case of Moveable Knee-joint three and a half years after operation for extensive tuberculous disease. The limb had remained in a plaster-of-Paris splint for two years. No attempts had been made to produce movement.—Mr. T. CRISP ENGLISH referred to a case of tuberculous disease of the ankle in which spontaneous movement had supervened after operation and also to a case of acute septic arthritis of the knee-joint following gonorrhœa in which similar results had been obtained after freely opening the joint.

Dr. F. PARKES WEBER exhibited a case of Polycythæmia with Enlarged Spleen and Chronic Erythromelalgia The patient was a married woman, aged 36 years, who had previously had good health but after her last confinement, seven years ago, she suffered from "inflammation of the womb" with swelling of the whole of the left lower extremity, which lasted a month. Burning sensations in both feet appeared about three years ago and when first seen in 1903 the feet were turgid with blood, hot and painful. All these signs were much more prominent in the left foot. At the present time the erythromelalgia was practically limited to the left foot, the skin over which presented several discrete purplish patches. The spleen was enlarged but there was no cyanosis. An examination of the blood showed that the hæmoglobin was about 125 per cent of the normal; the red cells were 9,000,000 per cubic millimetre and the white cells were 8100. Polymorphonuclear leucocytes were 73·75 per cent. The heart and lungs were normal The pulse was 88, regular, and of rather increased tension —Dr JAMES GALLOWAY said that Dr Weber's case appeared to resemble the original conception of erythromelalgia as described by Weir Mitchell, for arterio sclerotic changes were certainly not prominently marked in this case. Many of the cases recently described showed that the condition could be well simulated as a result of vascular degeneration and he referred to a case under his own care in the Charing Cross Hospital from an examination of which he had come to the conclusion that cases of redness, pain in one extremity, leading to necrosis, in an adult over middle age were more likely to be due to ischæmia of arteriosclerotic origin than to true erythromelalgia. He thought, moreover, that a revised classification of these cases was called for, based upon the blood changes rather than upon the actual condition of the vascular walls.—Dr. WEBER replied.

Mr. T. H. OPENSHAW showed (1) a case of Firm Ankylosis and Contracture of the Left Knee treated by elastic steel bar traction in a patient, aged 15 years, who had been able to walk about during the application of the apparatus; and (2) a case of Osteo arthritis of the Knee-joint following a Fracture of the Femur, improved after removal of pressure by means of a splint which had transferred the weight of the body from the pelvis to the ground, thus giving the affected joint rest.—Mr. LAWRIE H. MCGAVIN took exception to the term "osteo-arthritis" being applied to the case. The pupillary changes suggested Charcot's joint disease.—Dr. W. P. HERRINGHAM concurred in this view.—Mr. OPENSHAW admitted that the case might be one of tabetic arthropathy but said he had shown the case mainly to demonstrate the value of removing pressure from the joint by the appliances exhibited.

Dr. W. J. HARRIS exhibited a girl, aged 20 years, the subject of Acromegaly. The disease was in an early stage, the symptoms having only appeared about two years ago. She had suffered from slight epileptiform attacks and headache. Prognathism was well marked and the hands were enlarged. There were no urinary or ocular changes. She was 5 feet 5 inches in height and appeared to be still growing.

Dr. W. LEE DICKINSON showed a woman, aged 27 years, with Congenital Heart Disease. She was not cyanosed and there was a long rumbling murmur audible in the second left interspace close to the sternum, occupying the whole cardiac cycle, accompanied by a thrill. The pulmonary second sound was indistinguishable. A provisional diagnosis of patent ductus arteriosus was made.—Dr. WILLIAM PASTEUR asked whether the murmur was heard at the back.—Dr. HERRINGHAM referred to the great difficulty which was almost always experienced in arriving at such a diagnosis and suggested that the lesion was chiefly confined to the pulmonary artery.—Dr. HARRIS agreed in the diagnosis of patent ductus arteriosus and said that the murmur bore a strong resemblance to that which he had heard in a case where an aneurysm of the aorta had ruptured into the pulmonary artery.—The PRESIDENT also concurred in Dr. Dickinson's diagnosis and remarked that several cases had been recorded in which the diagnosis of patent ductus arteriosus made during life had been subsequently confirmed at the necropsy and he referred to one published by the late Dr. Hilton Fagge in the Guy's Hospital Reports in which a long wavy murmur was heard in that situation.—Dr. DICKINSON replied.

Mr. R. P. ROWLANDS showed a case of Congenital Malformation and Deformity in a woman, aged 30 years. The principal defects were absence of the ear and seventh and eighth cranial nerves. There were complete facial paralysis and nerve deafness on the left side. Portions only of the external ear were present. There was also an absence of the radius and part of the humerus on the same side, with abnormal smallness of the shoulder, scapula, and clavicle. Two metacarpal bones were absent while there were only four carpal bones.—Mr. MCGAVIN inquired as to the condition of the Eustachian tube upon the affected side and Mr. ROWLANDS replied that this canal was present but that the catheter passed a shorter distance than normal, the tympanum being absent. The non-development of the two cranial nerves, including the pars intermedia, explained the loss of taste which also existed over the left half of the tongue.

Mr. ROWLANDS also showed a case of Premature Puberty in a child, aged two years, in whom the external genitals were similar to those of a boy aged 15 years. In the few recorded cases of this condition it had been generally found that senile changes commenced at a much earlier age than usual. Such cases appeared to represent a reversion to the lower animals.

Mr. CHARTERS J. SYMONDS exhibited a man, aged 45 years, with Gangrene of the Tips of the Fingers of Both Hands. The condition had begun two years ago. He was a horse-keeper but had not been exposed to cold more than this occupation would suggest. There was no arterial or nervous disease or any diabetes. The patient was under the care of Mr. C. H. Golding-Bird at Guy's Hospital.—Dr. PASTEUR thought that the possibility of Raynaud's disease could not be excluded, especially as some cases of that disease went on to the more profound changes without the earlier ones being specially manifest.

Mr. SYMONDS also showed a man, aged 42 years, in whom a Spontaneous Fracture of the Neck of the Femur had occurred while he was kneeling to open a cupboard.—Mr. A. A. BOWLBY said that the fact that one of the earliest signs of tabes dorsalis might be spontaneous fracture was hardly sufficiently appreciated. He referred to two cases in which this accident preceded all other signs of the disease.—Mr. SYMONDS replied that there were as yet no definite signs of locomotor ataxy in his case with the exception of a suspicion of some insufficiency of the ocular muscles.

EDINBURGH OBSTETRICAL SOCIETY.

Obstructed Labour.—Thyroid Relations in Obstetrics and Gynæcology.—Effects of Thyroidectomy.—Exhibition of Specimens.

A MEETING of this society was held on April 13th, Dr. N. T. BREWIS, the President, being in the chair.

Professor JARDINE read Clinical Notes on a series of 22 cases of Obstructed Labour, including eight cases of induction of premature labour, four cases of symphysiotomy, and ten cases of Cæsarean section. During 1903 Professor Jardine and his colleagues treated 703 cases in the Glasgow Maternity Hospital. Among these were 98 cases of contracted pelvis—an extraordinary proportion of 1 in 7; this, however, did not by any means include all but only those in which there was difficulty in delivery. Details of eight cases of induction of labour and four cases of symphysiotomy were given. In the eight cases of induction of labour the conjugatæ veræ varied from three and a quarter inches to three and five-eighths inches; seven of the mothers recovered and one died. In the first of the four cases of symphysiotomy the patient was a tripara, having a conjugata vera of three inches; her previous deliveries had been by craniotomy. The symphysis was opened by cutting directly down on it; forceps was applied and the head was extracted without difficulty in the Walcher position; the child was alive and weighed seven and a half pounds. Strong catgut sutures were inserted through the fibrous structures and the wound was closed with silkworm gut. The patient recovered and was able to walk without inconvenience. In the second case the woman was a quintipara, having a conjugata vera of three and three-quarter inches. Former children had been born with difficulty with the aid of forceps, one child being dead. In this labour forceps failed to effect delivery so symphysiotomy was performed. Even then considerable traction was required before the child was born; the infant was alive and weighed 11½ pounds. The patient recovered. In the third case the woman was a primipara, having a conjugata vera of three inches; the pelvis was flattened and generally contracted. In performing the operation difficulty was experienced in dividing the symphysis half-way down. As this might have been due to a bend the knife was turned a little to the left when the bone suddenly yielded and the joint gaped. Professor Jardine found that the bone had given way into the obturator foramen and at the same time the left ramus had fractured about the junction of the ischium and os pubis. The child was delivered alive by forceps, the weight being seven and a half pounds. During delivery the fractured end of the ramus caused laceration of the vagina. The symphysis and fractured ramus were sutured with catgut and the patient was afterwards douched and packed carefully. She made a good recovery and there was good union of the bones. In the fourth case the woman was a tripara, having a conjugata vera of three and a half inches. Previous children were born dead. After division of the symphysis the child was born alive with forceps, the weight being eight and a half pounds. There was free hæmorrhage from the wound which was found to be due to the rupture of the distal end of the urethra from the vaginal wall, but after the insertion of a catheter this was united by sutures. The patient's progress was satisfactory. It was doubtful whether symphysiotomy would become a favourite operation. There was great risk of laceration if much separation was required to effect delivery. Another objection was the prolonged nursing required after the operation. To obtain union the patient must lie very still which was very trying, especially when the calls of nature required attention. Convalescence in these cases varied from 31 to 42 days. Professor Jardine then gave details of ten cases of Cæsarean Section. All the mothers recovered. The method of operating consisted in making an incision about five inches in length high up, so that two-thirds of it lay above the umbilicus, and then incising the uterus longitudinally in the middle of the anterior wall so that the top of the incision would be at the fundus. Cameron's pessary was generally used to prevent bleeding from the uterus while incising it. The child was delivered by grasping a leg. In nearly every case the child required to be resuscitated, probably due to the effect of the cold on opening the abdomen causing the child to make inspiratory efforts and to draw liquor amnii into the lungs. The placenta was found on the anterior wall in nine-tenths of the cases. Catgut sutures were employed for the uterus and silk to tie the tubes. Silk and celluloid thread for uterine sutures often gave great trouble, even for months afterwards. If a patient had been in labour for some time and repeatedly examined without aseptic precautions the risks from Cæsarean section were greater than if she had been under observation before labour and had been properly prepared for the operation. Sterilising the patient at the operation was best done by tying the tubes with silk and dividing them. This should only be done if the husband and wife desired it. Professor Jardine left the uterus and ovaries even if the patient had had her tubes tied.—The paper was discussed by Dr. HAULTAIN, Dr. JAMES RITCHIE, Dr. W. FORDYCE, and others.

The SECRETARY read a paper by Dr. R. C. BUIST (Dundee) on three cases illustrating Thyroid Relations in Obstetrics and Gynæcology. The first case was one of myxœdema with cystocele and prolapse in which ventrofixation was performed. The second case was one of myxœdema and pregnancy. Dr. Buist could only obtain record of one other case, that of Herrgott,[1] the patient being an undeveloped woman, aged 18 years, who had 12 eclamptic fits during labour and eight after delivery. There was only a trace of albuminuria. Dr. Buist's patient was 48 years of age and she had had 11 children. Labour occurred spontaneously, there were no fits, and the thyroid treatment was continued. The third case was that of a woman, aged 37 years, who had shown enlargement of the thyroid in successive pregnancies. Eventually she died from a malignant tumour in the neck.

Dr. H. OLIPHANT NICHOLSON read a communication referring to experiments in feeding made on thyroidectomised animals.

Dr. D. CHALMERS WATSON gave a Demonstration of Specimens illustrating the experimental influence of a pure raw-meat diet on the thyroid and parathyroid glands. The thyroid was increased to many times its normal size and was of the nature of a hypertrophy; the parathyroid also was greatly enlarged.

Dr. F. W. N. HAULTAIN showed a Calcified Full-time Fœtus which had been retained in the Abdomen for 41 years and which was removed post mortem.

Professor R. JARDINE (Glasgow) showed a Modification of Braun's Decapitating Hook in which a knife edge was inserted on the concavity of the hook, facilitating greatly the division of the structures of the neck.

HARVEIAN SOCIETY.—A clinical evening of this society was held on April 14th, Dr. C. Theodore Williams, the President, being in the chair.—Dr. Leonard G. Guthrie showed a man, aged 38 years, who during three years had gone through the following phases of Insular Sclerosis. In 1881 he had a temporary attack of hemianæsthesia and in 1894 paræsthesia of the hands and feet and loss of power in all the extremities with recovery in a fortnight. In 1895 he was admitted to the National Hospital for the Paralysed and Epileptic, Queen-square, with weakness of the lower limbs and difficulty in micturition (sphincter). Right-sided hemiparesis, with loss of sensation, tactile and painful, in front of the thighs, was found. There was no nystagmus or affection of the cranial nerves. Speech was normal, the knee-jerks were brisk, and there was no ankle clonus. The optic discs were normal. Recovery was apparently complete in about three months. In 1898 weakness of the legs reappeared and in 1900 he could not walk without help but again he improved and was able to return to work. In January, 1901, he was readmitted to hospital with loss of power and slight incoördination in the hands, ataxic spastic gait, exaggerated deep reflexes, and extensor plantar reflexes; there was no ankle clonus or other symptom. Sensation to pain and touch was blunted below the umbilicus. The patient improved steadily at first and anæsthesia practically disappeared. Then he had a relapse and became unable to walk without assistance, whilst there was marked increase in spasticity. Once more he improved steadily and could walk without help. At the end of 1901 he was slowly getting worse and his gait was very ataxic and spastic. At present there was very slight nystagmus on lateral deviation. The optic discs were normal. Speech was stuttering but not scanning or syllabic. There was no wasting of the muscles and sensation was normal. The muscular powers of the upper extremities were fair. There were very slight "intention" tremors. The abdominal and back muscles were paretic at times. The lower extremities were not wasted, ataxic, or spastic, but the muscles showed varying degrees of weakness of different groups. The gait was neither spastic nor ataxic but weak and uncertain. The knee-jerks were active, not exaggerated; there was ankle clonus (spurious) at times; the plantar reflexes were sometimes absent, sometimes extensor on one or both sides. The electrical reactions were normal. The muscular paresis varied greatly and was worst under the influence of emotion or after fatigue. If left alone he could get up, wash and dress himself, and walk about with the aid of sticks, and he seldom fell. But if notice was taken of him he became flurried and nervous with walking and presently fell like a tree and became completely paraplegic and exhausted for the time being. The influence of emotion in increasing general paresis was so marked that he (Dr. Guthrie) had regarded the condition as one of functional myasthenia until the history clearly pointing to relapsing and remittent insular sclerosis was forthcoming.—Dr. J. S. Risien Russell and Dr. Wilfred Harris took part in the discussion.—Dr. Risien Russell showed a case of Myasthenia Gravis in a young woman, aged 26 years, whose illness began about a year ago and in whom many of the characteristic phenomena of the affection were present, including the myasthenic reaction on faradic excitation by the muscles. The symptoms were not, however, always made worse by muscular exertion, nor were they more pronounced at the menstrual period, and they disappeared in a remarkable manner ten months ago but returned eight months later. Some impairment of resonance over the manubrium sterni suggested the possibility of enlargement of the thymus gland.—Dr. Guthrie called attention to the association of thymic and mediastinal growths with myasthenia gravis.—Mr. J. Jackson Clarke showed a girl, aged seven years, on whom over two and a half years ago he performed Costotransversectomy for obstinate paraplegia due to tuberculosis at the level of the fourth dorsal vertebra. The patient was shown at the Clinical Society two years ago, since when the mode of treatment had been successfully followed in similar cases. Paraplegia in spinal disease frequently yielded to rest and general treatment but there were two indications for operation—firstly, when total motor and sensory paralysis, including the bladder, supervened rapidly, and secondly, when in the more ordinary type of case in which the paralysis was chiefly motor rest had been given a fair trial without success. If performed with due care costotransversectomy was less dangerous than laminectomy and on other grounds was preferable to it. In the present case there was no return of paralysis after the operation and the patient was allowed to walk with the spine well supported by a modified Chance's splint.—Dr. Edmund Cautley showed a case of Cerebral Syphilis. The patient was a man, aged 22 years, who had been admitted to the Metropolitan Hospital for lassitude and headache of three months' duration and vomiting for three weeks. He was treated at the Lock Hospital for 18 months and still showed the remains of a specific rash. His hair came out a year ago and on admission he was almost bald. His mental condition was dull but he had distinctly improved under a month's treatment and there was a free growth of white hair becoming dark in places. The knee-jerks were exaggerated, there were no ocular changes, and the headache had ceased. The condition was doubtless due to a mild form of endarteritis.—Dr. Wilfred Harris showed two cases of Lead Paralyses. These cases illustrated two types of lead paralysis; both showed the ordinary form of wrist and finger drop with escape of the supinator longus and the extensor ossis and primi internodii muscles of the thumb. In addition one had complete paralysis of the two deltoids and supra- and infra-spinatus muscles, the remaining arm muscles escaping, while the other case had complete atrophy of the intrinsic muscles of both hands, a condition which was due to a symmetrical subacute poliomyelitis and which was permanent, while the forearm and upper arm paralyses were due to neuritis and would almost certainly recover.—Mr. T. Crisp English showed three cases. 1. A case of Goitre with unusual symptoms in which he had removed hypertrophied lateral and middle lobes. The patient, a girl, aged 17 years, had had exophthalmos, tachycardia, palpitations, and tremor, while there had been also a myxœdematous condition of the skin; the operation had been performed on account of severe dysphagia. This combination of symptoms was rare The general conditions had improved. 2. A case of a large Gumma of the Knee-joint which was of old duration and was sloughing. 3. A case of Encephalocele in the left frontal region which was increasing rapidly in size and demanded early treatment if such were advisable.—Mr. E. Percy Paton considered that the interesting feature of the second case was the thickening of the synovial membrane and possibly cartilage changes which in other circumstances might lead to an erroneous diagnosis of osteo-arthritis.—Mr. E. Laming Evans showed a case of Congenital Absence of the Fibula in a female, aged four months. The whole leg was small; the characteristic curve in the lower third of the tibia with a depressed scar or dimple at the point of maximum convexity was present. The metatarsal and phalangeal bones of the fifth toe were absent; the foot was in well-marked equino-varus. A skiagram confirmed the complete absence of the fibula. No history of deformity in the family or of injury during pregnancy was obtainable.

---

[1] Annales de Gynécologie et d'Obstétrique, July, 1902.

British Balneological and Climatological Society.—A meeting of this society was held at Hanover-square, London, W., on April 14th, Dr. Alfred F. Street (Westgate), the President, being in the chair.—The discussion on Obesity, which was opened by Dr. Leonard Williams at a previous meeting on Feb. 3rd, was reopened by Dr. William Bain (Harrogate). Dr. Bain dealt with the subject from the physiological standpoint. Excessive fat deposition was either due to an abnormal production of fat or to diminished oxidation. Fat formation was chiefly linked with carbohydrate metabolism. The normal utilisation of fat was also considered. As regarded treatment he said that the essential elements were regulated exercise, the restriction of the carbohydrate and fatty materials of the food, living an outdoor life if possible, accelerating heat loss, and combating any tendency towards anæmia.—Dr. Robert Barnes considered that to elucidate the question of obesity it was desirable to study the conditions of race, climate, and food. He had been struck with the extreme leanness of the Arabians of the working class, most of whom were extremely active and fed mainly on vegetables. This applied also to the horses and cattle which were sparingly fed. He had noticed some exceptions in the persons of policemen and dragomans and other people who came in contact with the visitors. On the northern coast of the Mediterranean he noticed the general fatness of the inhabitants. Was this because they fed largely on macaroni?—Dr. S. D. Clippingdale referred to the frequency with which a state of obesity was found in persons of high intellectual capacity, contrary to the usual belief, giving several instances in the present and past times, and referred to Julius Cæsar's well-known dislike of thin persons.—Dr. E. Symes-Thompson pointed out that as life assurance experience showed how dangerous to life obesity was proved to be it behoved them to utilise to the utmost spas and climate treatment, to encourage exercise, to promote metabolism, and to raise the health level of their patients.—Dr. Alexander Morison maintained that undue mystery had been cast around both adult and infant feeding. The principles of nutrition were clearly known and their application was sufficiently clearly indicated by each case considered on its own merits. He pointed out the importance of separating obese cases with, from those without, anatomical organic disease. In the former the general force of the patient must be improved before his fat reduction by restricted diet was commenced.—Dr. W. Bezly Thorne drew attention to the fact that Bouchard placed obesity in the class of affections which he had denominated "l'arthritisme," that it was common in the subjects of [illegible] of which venosity was a recognised [illegible] as in those who were deficient [illegible] suffered from prolonged loss of blood. He recalled the fact that the obese were specially liable to angina pectoris and to death from syncope and to apoplexy consequent on atheroma. Such considerations, he said, pointed to a potent cardio-vascular factor in obesity and emphasised the danger of treating that condition on lines of arbitrary dietary restriction.—Dr. W. Ewart alluded to the distinctions between physiological stoutness which ran in families and needed no treatment and that which was pathological. The latter was generally admitted to depend upon relative deficiency in oxidation. This was to be remedied by various methods which had been fully discussed. The question arose whether oxygen itself, administered by inhalation, might not be of service. He was unable to furnish any definite results from systematic observations but his general impression was that the free use of oxygen tended to reduce rather than to increase body weight and he would be glad to hear the experience of other clinical observers on this point.—Dr. D. Baynes had found that high-frequency currents on alternate days with galvanism, using currents of from 80 to 150 milliampères, speedily reduced the most corpulent and quickly relieved the dyspnœa due to fatty heart. These currents were applied by large well-covered electrodes placed over the abdomen, loins, thighs, and buttocks. —Dr. Nightingale, after referring to the precautions taken in the tropics against chills, drew attention to the value of the high-frequency current in the reduction of obesity; he had found that there was an immediate loss of weight varying from a quarter to two pounds after each application of the current, and that it was possible to decrease the weight by from 7 to 14 pounds in a month without any injurious effect.—Dr. Joseph Groves (Carisbrooke) said that on entering the world everyone was different; in passing through life everyone differed in environment and occupation and in middle age the resultants of various influences necessarily differed widely. The duty of the physician was to obtain conformity to nature's laws and not to a type. Special dietetics and "high frequency" notwithstanding many people continued stout and the pressure of over-exertion upon organs worn by the stress of existence was checked. They might as well try to treat obesity apart from natural laws as to deal with ventilation without reference to the law of the diffusion of gases.—Dr. Septimus Sunderland considered it was necessary to warn patients who showed signs of commencing pathological corpulency to begin to take the requisite precautions against its increase in the early stage; they would then see fewer cases of excessive stoutness the reduction of which was sometimes attended with risk. He referred to the abuse of thyroid gland extract with which some people dosed themselves without medical advice and mentioned the case of a woman who had recently reduced her weight about one and a half stones in a few weeks by the self-administration of 45 grains of the extract daily. —The President said he wished that there had been put forward some explanation of the personal element as a cause of obesity and pointed out that this alone would suffice to condemn the distribution of printed dietary lists. He could not agree that abstinence from fluid at meals diminished the tendency to obesity only by providing space for the ingestion of more food but there did seem to be evidence that abundance of fresh air—i.e., increased percentage of oxygen —did so act, perhaps by hastening the oxidation of the food taken.—Dr. J. T. Leon (Southsea) and Dr. J. Braithwaite (Buxton) also made remarks.—Dr. Bain and Dr. Leonard Williams replied.

Epidemiological Society.—A meeting of this society was held on April 15th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. T. M. Legge, medical inspector of factories, read a paper on Industrial Anthrax, dealing with 211 cases reported to the chief inspector during the years 1899-1903 inclusive. These cases were about equally divided between workers in wool and worsted, hides and skins, and horsehair and bristles, with a few in other industries. The fatality was much less than formerly, averaging 26 per cent., and not differing greatly from that observed in France, Germany, and Italy, excepting the outbreaks reported by Eppinger among a group of rag sorters in Austria where 78 cases out of 88 were fatal. These, however, were of the internal form, to which five only of the 211 belonged. Of the 72 occurring among wool workers 56 were of persons employed in sorting and combing the classes of wools scheduled as dangerous, so that calculated on this limited number of workers the attack figure was 1·3 per cent. and for workers in horsehair factories, excluding those in brush and bristle works, it was 1·5 per cent. Of the 72 cases among wool workers 41 were in Bradford and 11 were in Kidderminster. Of the 69 derived from hides and skins 38 were in London and 18 were in Liverpool, while of those from horsehair 23 were reported from London, other towns and districts contributing from one to nine only in each group. The dangerous wools were those from China, Russia, Siberia, Persia, and Syria, and in like manner the cases of anthrax due to hides were almost limited to the ports of London and Liverpool. Of the whole 211 cases the seat of infection was the neck in no fewer than 84, the face and head in 77, the forearm in 16, and, strange to say, the finger only once and that open to doubt. The fatality was highest among patients attacked in the neck and face. In 143 cases excision of the pustule was practised but it was difficult to say what amount of benefit resulted from any one kind of treatment. Professor Sclavo of Siena had, however, prepared a serum from inoculation of sheep and had treated 164 consecutive cases with a fatality of 6·09 per cent., one woman recovering in whose blood the bacilli were already seen and the only fatal cases being those in which the patients were moribund when the injection was made. The question of disinfection was beset with difficulties, for no effective method of destroying the spores of anthrax was known except heat, the employment of which would be destructive of hides and wool. Current steam was, however, already extensively used in England, Germany, and elsewhere for horsehair and was found to be most successful and least, or practically not at all, injurious when at a temperature between 200° and 225° [illegible] to two and a half pounds for [illegible]ned wool, though formalin was [illegible]ax bacilli retained their vita[illegible] of the tanyard. In fact, save as regards horsehair, the only available means were thorough cleansing of the raw materials so far as possible by wet methods and with every precaution to prevent the diffusion of the dust which with all refuse should be burnt and not used, as it often was, for manure, nor should the waste water be turned into streams, at least unless after boiling, for many valuable horses and cows had been thus infected and lost. The workpeople, too, should be protected by clothes, plain, fitting closely round the neck, wrists, and ankles, kept at the factory and frequently boiled and washed; they should wear gloves and also respirators or veils when specially exposed to dust.—Dr. W. Arnold Evans, medical officer of health of Bradford, said that there were dangerous wools among the unscheduled ones and that he had found all disinfection to be ruinous to wools.—Mr. Webb, of Worcester, a horsehair manufacturer, said that he had in conjunction with the county medical officer and analyst conducted numerous experiments and cultures. He had often found the bacilli in the dust and had had some cases among his workpeople, but besides other precautions he had since 1897 employed current steam in a Lyon's disinfector at the moderate pressure and temperature recommended by Dr. Legge and by the German Home Office. It was remarkable that when the dust from carding contained no spores that separated by subsequent steaming often did, the moisture having detached organisms that had resisted mechanical processes. He described his visit to the factory of Signor Pachetti of Milan who employed 1500 workpeople and had independently adopted the same methods as himself.—Dr. W. H. Hamer said that he thought the 30 000 cases with 5000 deaths said to have occurred in ten years in Italy were incredible unless other diseases were included.—Dr. H. Franklin Parsons, in reply to Dr. H. T. Bulstrode's request for information as to non-industrial anthrax, said that it was occasionally met with among butchers and he believed that many cases occurring on farms were due to pollution of the streams. Cooking destroyed the bacilli for he knew a case in which the farmer and butcher who cut up the carcass of an infected animal both died within a week but no ill consequence followed the consumption of the flesh which, except the tongue, was all sold in the open market and could not be traced.—Dr. H. R. Kenwood, Mr. Wolf Defries, and others also took part in the discussion.—Dr. Legge, in his reply, said that of non-industrial anthrax 32 cases had been reported to him among butchers. These he believed to be far from all, but from the arms being oftenest the seat of infection the mortality was low. Anthrax was very prevalent in South America but in that country it was very mild in man. 200 cases without a death had been reported.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 22nd, Mr. C. Richardson, the President, being in the chair.—Dr. A. E. Porter read a paper on the Administration of Prophylactic Injections of Antitoxin to Persons who had been Exposed to the Infection of Diphtheria. He mentioned the results of this mode of procedure in Essex during the years 1900–01. Out of 136 persons in 24 households only one subsequent case occurred after the injection and this was a very mild attack. Of the remaining eight persons in the same houses who were not injected there were three cases of diphtheria. During the same epidemic there was another series of 24 similar households in which no injections were given and one-sixth of all the inmates, excluding the primary cases, subsequently contracted diphtheria. In neither series was it possible to maintain satisfactory isolation. The employment of prophylactic injections in Cambridge, Toronto, New York, and Chicago was quoted. Dr. Porter considered that for the majority of persons exposed to infection 500 units conferred protection for about three weeks. Failures occurred in a small percentage of instances but the subsequent attacks were of a very mild nature and the administration of antitoxin was especially advisable during [illegible] of diphtheria when ordinary measures [illegible] also in the case of institu[illegible] was mentioned that among persons so protected a considerable proportion were infective and that care should consequently be taken to prevent them from mixing with unprotected individuals.—Dr. A. H. Bampton, Dr. J. G. Sharp, and Dr. W. H. Cheetham took part in the discussion.—Dr. A. F. Dimmock described a New Method for the Estimation of Uric Acid in Urine. He had devised this method in conjunction with Mr. F. W. Branson, F.C.S., their aim having been to work out a simple process which did not require much time. A definite amount of urine was saturated with chloride of ammonium and the precipitated urate of ammonium was collected and carefully washed. This was placed in a closed bottle and by reaction with hypobromite of sodium the evolved nitrogen was collected in an apparatus similar to that used for the determination of urea. The volume of gas was noted and from this the uric acid present in the urine was calculated. Experiments with chemically pure uric acid had given excellent results.—Mr. H. J. Roper read notes of Two Cases of Intussusception which had occurred in Children and which he had reduced after abdominal section. In one case the symptoms had lasted four days and in the other for less than 24 hours. Both children recovered. Their ages were eight and a half years and 12 months respectively.—Mr. H. Littlewood and Mr. R. Lawford Knaggs took part in the discussion.—Mr. J. Tregelles Fox read a paper on the Mechanism of the Alimentary Canal. He discussed the mode of propulsion of its contents and advanced the opinion that a mechanism different from mere peristalsis could be traced in most if not all the divisions of the human alimentary tract. The object of the paper was to promote a better comprehension of the causes of constipation and allied complaints. A typical diurnal revolution or cycle of the alimentary system was described and its modifications to suit the various climates, races, and occupations of mankind were alluded to.—Cases [illegible] were shown by Mr. G. O. Hayes, [illegible] Barrs, Mr. Littlewood, Mr. [illegible] Moynihan, Dr. J. B. Hellier, and others.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on April 21st, Dr. James Barr, the President, being in the chair.—Dr. K. A Grossman exhibited two different colonies of Tænia Solium from the dog—one from a pug and the other from a collie. They showed marked differences—viz., that from the pug had a club shaped head, a long thin neck, was flat and transparent, and had small hooklets arranged in irregular rows three deep; that from the collie was larger and altogether thicker set, showed hardly any neck, and shorter, thicker, and more opaque proglottides. The hooklets were 16 in number and much larger than those in the worm from the pug.—Mr. R. O. Dun showed the following specimens: 1. Volvulus of the Small Intestine in a child in whom the whole of the jejunum and ileum was implicated. Two complete twists of the root of the mesentery had occurred from right to left. There was mesenteric disease present in the shape of numerous hard enlarged glands, probably tuberculous in nature. From the position of the cæcum which occupied the epigastric region when the abdomen was opened it seemed probable that a common mesentery had existed for the small intestine, cæcum, and ascending colon. 2. Embolism of the Pulmonary Artery obtained from a child, four years old, who died with extreme suddenness four hours after osteotomy of both tibiæ—Dr. A. S. F. Grünbaum showed Sections from the Lung and Bronchial Glands of a mouse which had been infected per os with blastomycetes from a carcinoma mammæ. The changes were those usually seen, the interest being in the mode of infection.—Dr. W. B. Warrington demonstrated the nature of the Cells and Micro-organisms found in the Cerebro-spinal Fluid withdrawn by lumbar puncture in cases of Tuberculous Postero-basic and Vertical Meningitis.—The Stomach, Intestines, and Liver were shown from a case of poisoning by corrosive sublimate under the care of Dr. J. Lloyd Roberts.—Dr. Grünbaum gave a demonstration of models illustrating Ehrlich's Theory of Immunity.—Dr. T. R Glynn showed a large series of coloured drawings illustrating various Lesions of the Heart.—Mr. F. T. Paul reported two cases of Cancer of the Bladder in which he removed during life the growths shown. The first case occurred in a female, aged 63 years. The growth was three-quarters of an inch in diameter, it was removed suprapubically with bladder scissors, and the base was cauterised with Paquelin's cautery. The second case was that of a female hospital patient, aged 69 years. In this case the tumour measured two inches across and was removed with the knife after splitting the urethra back well into the bladder through the vagina. Histologically the tumours were examples of the large-celled carcinomata of the bladder epithelioma type, but showed no nest cell groups. In the second case the carcinoma began in a small villous tumour which was still present at the upper end of the growth.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held at the West London Hospital on April 8th, Dr. Seymour Taylor, the President, being in the chair.—Dr. P. S. Abraham showed a case of Molluscum Contagiosum in a girl, aged eight years. He also showed a case of Creeping Linear Dermatitis. The patient, a delicate, ill-nourished girl, aged seven and a half years, had suffered shortly after birth from an abscess in the right breast, which had gradually travelled right across the chest, leaving a serpiginous, slightly pigmented irregular line, marked by numerous whitish pits, evidently the sites of the little abscess. The case strongly resembled the "creeping eruption" described by Dr. R. H. Lee in 1894 and 1884, and to some extent those cases due to the subcutaneous burrowing of an œstrus larva. The term "larva migrans" had been applied to all these cases of creeping linear lesions, in Dr. Abraham's opinion incorrectly, as a certain number, like the case shown, had nothing to do with a migrating larva. Excision of the advancing end of the creeping line and careful microscopic examination was the treatment proposed.—Dr. H. Campbell Pope referred to a case of Molluscum Contagiosum recently under his care in an adult in which there were a large number of mollusca scattered over the body. The case had at first been considered to be one of varicella but the duration of the eruption and the typical appearance of the tumours led to a correct diagnosis. The application of pure carbolic acid to the individual tumours, a few at a time, effected a rapid cure.—The President showed a woman, aged 23 years, who had been admitted into the hospital on account of Extreme Emaciation. She had steadily refused food except under great persuasion for a period of six months. Mentally she was suspicious and obstinate and at times refused to reply to any questions. There was no evidence of physical disease and the case was considered to be one of anorexia nervosa. At first forced feeding by a nasal tube was necessary but gradually the patient was induced to take a fair quantity of nourishment. Such cases usually recovered under Weir-Mitchell treatment but the mental condition of many of these patients was on the border-line of insanity.—Dr. J. D. E Mortimer said that unremitting supervision was necessary in the treatment of such patients, as it was impossible to foretell whether sudden suicidal impulse might not arise. The association between melancholia and malnutrition was a close one and he agreed with Dr. T. S Clouston as to the necessity for "feeding up" and "fresh air" in such conditions.—Dr. J. B. Ball showed a case of Melanotic Sarcoma of the Soft Palate. The patient, a man, aged 53 years, had noticed black patches on the roof of his mouth for about two years and about 15 months later a growth appeared on the soft palate. This led to no inconvenience till three weeks ago when hæmorrhage caused him to seek medical advice.—Dr. Ball also showed a girl, aged 17 years, who had come under his care four weeks previously complaining of Swelling of the Left Cheek. The case was considered to be one of antral cyst. The treatment consisted in evacuation of the fluid through the anterior wall of the antrum and recovery was rapid without deformity of the face—Mr. G. A. Garry Simpson showed a case of Chloasma affecting the Neck.

THERAPEUTICAL SOCIETY.—A meeting of this society was held at the Apothecaries Hall, London, on April 19th, Dr. C. Cooper being in the chair.—Dr Herbert S. French read a paper on Some Experiments upon Drugs which are said to Increase the number of Leucocytes in the Blood. After describing the views of Metchnikoff and Ehrlich and Walker's experiments he said that he had found the leucocytes in his own blood amounted to 13,000 per cubic millimetre. He took nuclein by the mouth and hypodermically in increasing doses but he never found more than 13,125 leucocytes to the cubic millimetre of his blood. Then hypodermic injections of sodium cinnamate were tried but no increase of leucocytes occurred, and, lastly, collargol was injected in increasing doses. This raised the leucocytes to 22,187 per cubic millimetre, but caused fever, headache, and depression.—A note from Dr. T. B. Belgrave of Australia, a corresponding Fellow, was read inclosing the translation of a letter from Dr. Hahl, Imperial Governor, German West Guinea, stating that no parasite of a mosquito had been found there, but Dr. Dempwolff, the leader of one of the malaria expeditions, stated that a species of notonecta found in the pools devoured the larvæ of the anopheles and he suggested that the notonecta should be bred where malaria existed.—A paper from Mr. J. Maiden, director of the Botanical Gardens at Sydney, a corresponding Fellow of the society, was next read by the Secretary. The subject of the paper was Plants which Induce Eczema, the following being enumerated and instances of the irritation which they caused being given: (1) Phlebolium argenteum (rutaceæ) called blister plant; (2) and (3) (meliaceæ) dysoxylon Richii and dysoxylon Muelleri (red bean); (4), (5), and (6) (anacuardiaceæ) rhus radicans (the poison ivy), rhus diversiloba (the poison oak), and rhus vernix (the poison sumach or poison elder); (7) (leguminosæ) castanospermum Australe (the black bean); (8) and (9) (myrtaceæ) eucalyptus maculatus (spotted gum), and eucalyptus hemiphloia; (10) cassania aculeata (dogwood); (11) (compositæ) pyrethrum parthenium (feverfew); (12) and (13) (primulaceæ) primula obconica and primula sinensis; (14) and (15) (euphorbiaceæ) excæcaria agallocha and excæcaria parviflora; (16) (coniferæ) thuja Douglasii; (17) (liliaceæ) hyacinthus orientalis; and (18) (aroideæ) richardia Æthiopica (the arum lily). All these excited irritation of the skin by contact and some, such as the rhus and eucalyptus, even by proximity.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 22nd, Dr. Leslie Durno, the President, being in the chair.—Dr. J. S. Risien Russell read a paper on the Diagnosis and Treatment of Tumours of the Spinal Cord in which he laid stress on the fact that in their earlier stages cases of the kind were frequently mistaken for neurasthenia and hysteria. He quoted examples of this and pointed out what physical signs were present in the cases which were not in accord with the diagnosis of a functional affection and which of them made compression of the cord the most likely organic lesion present. Lumbago and sciatica were also often diagnosed in these cases and sometimes the pains were mistaken for those of tabes. It was not always easy to distinguish cases of syphilitic meningo-myelitis except when there were signs of concomitant syphilitic affection of intracranial structures, although the results of treatment might help to decide the question. Another disease that sometimes caused difficulty was subacute combined degeneration of the spinal cord, in which, however, pain did not antedate the motor and sensory paralysis in the way that it usually did in extramedullary tumours, while evidence of upward extension of the mischief might further prove of assistance in the diagnosis. Intramedullary tumours might readily be mistaken for syringomyelia, as in a case which he quoted, but trophic lesions of the skin, nystagmus, and curvature of the spine were absent. The differential diagnosis between intra- and extra-medullary tumours was most important, because while nothing could be done for the former the latter allowed of some of the most brilliant achievements of modern surgery. When there was good reason to suspect gumma mercury and iodide of potassium should be tried, but valuable time ought not to be lost when there were signs of progressive destruction of the spinal cord. In any case in which a non-syphilitic tumour was diagnosed and localised it should be removed with as little delay as possible unless the cord had already been destroyed beyond hope of repair.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on April 20th, Dr. E. S. Reynolds, the President, being in the chair.—Dr. Nathan Raw made a communication on the Method of Infection of the Human Body by the Tubercle Bacillus and exhibited several specimens illustrating such invasions. He was of opinion that human and bovine tuberculosis were distinct varieties of the same disease and that the bacilli were culturally and morphologically different. Abdominal tuberculosis in children, together with enlarged glands and strumous joints, he considered were in reality bovine tuberculosis conveyed to the alimentary canal by tuberculous milk. He was also of opinion that acute miliary tuberculosis was generally bovine in origin and was not true human tuberculosis. He believed that the human body was attacked by two distinct varieties of tuberculosis.—Mr. W. P. Montgomery read notes of a case of Excision of a Congenital Dilatation of the Sigmoid Colon and showed the specimen.—Mr. F. A. Southam made some remarks on a series of 120 operations for the Removal of Vesical Calculi and showed the specimens which included examples of encysted calculi, spontaneous fracture, calculi containing foreign bodies as their nuclei, and so on. In 49 cases the calculi had been removed by lithotrity, 14 of the patients being boys under ten years of age. In 63 cases lithotomy had been performed, the lateral operation in 17 patients and the suprapubic in 46 patients. In ten cases there was a recurrence after operation—viz., in five patients after lithotrity and in five patients after lithotomy. No instance of recurrence was met with in children or in adults under 50 years of age.—Other preparations were shown as card specimens.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—A meeting of this society was held on April 11th, Mr. A. E. Maylard, the President, being in the chair.—Dr. G. B. Buchanan showed as a fresh specimen a Segment of Bowel with a Meckel's Diverticulum excised for the relief of obstruction. The tip of the diverticulum was not attached, nevertheless it and its mesentery had become twisted in such a manner as to produce a gradual strangulation of the bowel.—Mr. J. R. Riddell showed several cases of Rodent Ulcer, Lupus, &c., treated by the x rays and other electro-therapeutic means. Several of the cases were previously shown to the society in February, 1903. The results of the treatment had been most satisfactory.—Dr. A. N. McGregor and Dr. R. Ramsey gave a demonstration and read notes of experiments undertaken to determine the relative efficiency of some surgical dressing materials as absorbents of the discharges from wounds. The most efficient was found to be a cylinder of wood-wool and next to it was lint. The favourite packing (iodoform gauze) was found relatively very inefficient; some samples, indeed, were almost water-proof.—Dr. W. W. Christie (for Mr. J. Walker Downie) read notes of two recent cases of Crico-thyrotomy for the Removal of Intralaryngeal New Growths. Dr. A. R. Ferguson showed microscopical sections of the tissues removed and read a pathological report upon them.

WIGAN MEDICAL SOCIETY.—An ordinary meeting of this society was held on April 14th.—Mr. W. Mitchell Roocroft, who was in the chair, showed a patient (male), aged 45 years, on whom he had performed Gastro-jejunostomy for Cancer of the Stomach and adjacent organs three months previously. The patient recovered and had increased considerably in weight.—Mr. Roocroft afterwards gave his presidential address on Ankylostomiasis which was attentively listened to and much interest was evinced in the subject.

Reviews and Notices of Books.

A Text-book on the Practice of Medicine. By JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College, Philadelphia; Physician to the Medico-Chirurgical Hospital. Illustrated. Sixth edition. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 1275. Price 24*s.*

IT must be a source of gratification to Professor Anders that although the fifth edition of this work, of which two large reprints were made, was issued only two years ago yet another edition has now been found necessary. The practical applications of the results of experimental medicine to the diagnosis and the treatment of disease have been again made the feature of the work. The general plan and principles of classification adopted in the previous editions have been preserved, although the subject-matter has been thoroughly scrutinised and carefully revised. In our notice of a previous edition we commented favourably on the use which was made of tabular presentations of points in differential diagnosis and this plan has been retained. Those subjects which have recently attracted considerable attention, such as the mosquito-borne diseases (malaria and yellow fever), bacillary dysentery, cholecystitis and the use of the x rays in the diagnosis and treatment of disease, have all received a due share of attention. Brief descriptions have also been introduced of certain conditions which were not included in previous editions. Paratyphoid fever is noticed, this term being applied to a group of affections that closely simulate typhoid fever clinically but are due to an essentially different microbic cause; there is also an absence of intestinal ulceration; the condition which has been termed the "fourth disease" is also mentioned. The subject of trypanosomiasis only receives brief attention, the report of the Commission of the Royal Society not having been issued when this edition was in preparation. Attention is also directed to a rare form of aphasia—trans-cortical or conduction aphasia—originally supposed to be due to a lesion in the fibres uniting the centres of audition and motor speech. Examination has shown, however, that the lesions are of the most various description. A short account is given of adiposis dolorosa, a condition in which masses of fat are deposited irregularly in the subcutaneous tissues of the body with tenderness and spontaneous pain in these masses and derangement of the menstrual functions. A few remarks are devoted to a peculiar disease of the central nervous system termed amaurotic family idiocy. It is characterised by the occurrence, a few months or a few years after birth, of marked impairment of intelligence and gradually progressive loss of vision. The pathology of the disease is not known. We are informed in the preface that the changes and additions in the section devoted to diseases of the nervous system are from the pen of Dr. Joseph Sailer.

From the point of view of the medical practitioner this work is a most useful one. It is essentially a text-book on clinical medicine and as such will be found valuable for purposes of reference.

The Law relating to Pauper Lunatics. By SYDNEY DAVEY, B.A., LL.D., Barrister-at-Law. London: The Poor-law Publications Co. 1903. Pp. 177. Price 5*s.* 6*d.*

LIKE most of the manuals of lunacy practice this book consists of extracts from various statutes relating to insanity with explanatory notes and cross references. Inasmuch as it deals almost exclusively with pauper lunatics the reader interested in this class can find what he wants without being overwhelmed by "the literature of the subject" as contained within the covers of the unwieldy treatises of Archbold or Renton. Moreover, the work under review is up to date and fortified by recent decisions in the courts and as its author is a gentleman of considerable experience in matters relating to the Poor-law it may be safely recommended to the notice of boards of guardians and their officers, medical or other. It must be remembered, however, that Mr. Davey writes as a lawyer, not as one actually concerned in applying the provisions of the Lunacy Acts to the cases of insanity that the medical man meets with in practice, and consequently, although his opinions are perfectly sound, they are not necessarily always to be followed strictly. Thus in dealing with the definition of the term "pauper" as implied in Section 18 he inclines to the view that the words "in such circumstances as to require relief for his proper care" bring the case within Section 13. He is quite possibly right but Section 14 is the one which the Commissioners in Lunacy regard as the proper one and Section 20 is the one which relieving officers employ. It is a distinct convenience to regard the transfer to a workhouse and the reception there under the last-mentioned section as equivalent to relief and until the courts decide otherwise we see no reason for adopting the suggestion that such a construction is fallacious. Similarly, in spite of the opinion given by the Law Officers of the Crown in January, 1901, justices often adhere to the procedure formerly in vogue in dealing with cases under Section 20 instead of following the more orthodox route which requires the workhouse medical officer to assume the responsibility of detaining the alleged lunatic under Section 24.

There are one or two points concerning the duties of medical men upon which we have sought information in vain. For example, it is not explained what is to be done f the workhouse medical officer, acting under Section 24 (i.), does not see eye to eye with the workhouse master acting under Section 20 as to what constitutes proper accommodation in the workhouse.

A section deals with soldiers, seamen, and marines who become insane. The Army Act, 1881, which is as far back as Mr. Davey goes, was not retrospective and there are still military lunatics who do not fall within its provisions. A note dealing with these might be added to a future edition. The portion of the book concerned with the maintenance of paupers in asylums is commendably full and should prove very useful. Altogether the work is an excellent one and Mr. Davey has dealt with a complex and difficult subject n a manner which is, on the whole, quite satisfactory.

A System of Physiologic Therapeutics. Edited by SOLOMON SOLIS COHEN, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College; Physician to the Jefferson Medical College Hospital. Vol. VIII: Rest, Mental Therapeutics, Suggestion, by FRANCIS X. DERCUM, M D, Ph.D., Professor of Nervous and Mental Diseases in the Jefferson Medical College of Philadelphia; Neurologist to the Philadelphia Hospital. London: Rebman. 1903. Pp. 332. Price 12*s.* 6*d.*

THE nature and scope of this system of therapeutics are well known to our readers, reviews of previous volumes having appeared in our columns. The subjects discussed in the present volume are for the most part not to be found in the ordinary text-books but are, nevertheless, of great interest. Rest is of the utmost importance in treating certain diseases of the central nervous system, more particularly those which have a functional origin. Professor Dercum has succeeded in presenting the subject in a systematic manner. Simple physiological truths and clinical facts have so far as possible been placed side by side together with logical deductions in regard to treatment.

The first condition described is neurasthenia or, as Professor Dercum prefers to term it, "fatigue neurosis." This disease is a common one but the principles which guide its treatment are not always fully understood. A graphic description is given of its clinical features and then the application of rest as a therapeutic measure receives full consideration. The management of the diet in these cases requires close supervision and Professor Dercum gives full directions as to the nature and quantity of food which is required. It is rightly insisted on that the closest possible attention must be given to the execution of details when a "rest cure" is being carried out lest the whole purpose of the treatment should be defeated by some apparently trivial neglect.

A very good account is given of hysteria. Professor Dercum points out that hysteria is a genuine affection, the symptoms of which are in no sense assumed. The manifestations which are observed, though presenting great individual variability, consist of sensory, motor, psychic, and visceral phenomena so definite in character that taken together they constitute a distinct, well-outlined clinical whole. The method of treating the disease by means of rest is clearly and minutely explained and especial emphasis is laid on the difficulty which is frequently experienced in dealing with the visceral symptoms of hysteria, anorexia nervosa more particularly often proving a great obstacle to recovery.

The second part of the volume deals with the Therapeutics of Mental Disease. It is divided into two chapters, the first containing a consideration of the prevention of insanity and the general principles of the treatment of the insane and the second giving many useful hints as to the treatment of the special forms of mental disease, including drug habits and the insanities of intoxication.

The third and last part of the work contains some very sensible remarks on Suggestion. Professor Dercum points out that much unnecessary mystery attaches to this term. Unfortunately it has been associated very closely with hypnotism and has acquired an almost specific meaning. To make a suggestion, however, does not mean to impose a hallucination or a delusion upon a person in the condition of hypnotic sleep, but merely to convey to, or to arouse in, the mind of another some thought or idea in an unobtrusive manner. Physicians employ suggestion habitually, though most frequently they do so unintentionally and unconsciously. That it often powerfully affects the progress of a case, for good or for ill, must be admitted. It is rarely, of course, that suggestion alone is relied on; it is commonly as an adjuvant to treatment by other means that it proves of value.

Professor Dercum discusses the subject of hypnotism in an able and judicial manner and comes to the conclusion that it is only applicable as a method of treatment to an exceedingly limited number of cases.

This volume is well worthy of perusal and we can commend it to the notice of our readers.

The Eye, its Refraction and Diseases. By EDWARD E. GIBBONS, M D, Assistant Surgeon of the Presbyterian Eye, Ear, and Throat Hospital. New York: The Macmillan Company. London: Macmillan and Co., Limited. 1904. Pp. 472, small 4to. Price 21*s.* net.

ALTHOUGH the title of this work implies that the diseases of the eye will be described the author confines himself almost completely to the consideration of the physics and physiology of the eye. The reader will not find any account of the numerous inflammatory affections of the different tunics of the eye which occupy so large a space in all modern text-books, or of the diseases of the lids or lacrymal apparatus, or of cataract and the operations that have been devised for its removal, but upon the other hand he will obtain by a perusal of the 28 chapters into which it is divided an exceptionally full and complete knowledge of those facts which are partly based on theory and partly rest on experiment and which have of late years so wonderfully increased the interest that has always been felt in the functions of this organ. It is curious to notice that only half a century ago many of the headings of the chapters would have conveyed but little meaning even to those who were most familiar with the anatomy, physiology, and pathology of the eye. Such terms as retinoscopy, ophthalmoscopy, ophthalmometry, optometers, prismoptometry, astigmatism, visual acuity, and others indicate the new ground that has been broken and the immense strides that have been taken since the introduction of the ophthalmoscope.

The essential feature of the book is the very complete account that is given of the numerous instruments devised of late years for testing the different functions of the eye, including distance, colour, field of vision, motility, and refraction, and the examination of the tunics and media. Thus in regard to ophthalmoscopy alone four forms of ophthalmoscope employed by Loring as well as others by Knauer, Payne, and Roth are described and illustrated. The appearances presented by the retina and the choroid in health and in some forms of disease are described briefly but clearly. It need hardly be added that the details of the course pursued by rays of light in refraction by lenses and reflection by mirrors and the mode of production of the ophthalmoscopic image are given in full.

In discussing the cause of the light streak seen with the ophthalmoscope on the surface of the vessels the author remarks that it is a reflex streak formed by the reflection of light from the anterior convex surface of the column of blood within the vessels; at the same time he gives the opinions of Loring and Noyes that it is due to the light being condensed in passing through the column of blood in them and then reflected back by the subjacent tissue and the view taken by others that it is due to different causes in the arteries and veins—in the veins resulting from a reflection from the surface of the column of blood within them, whilst in the arteries it proceeds from the axial part of the blood stream.

Many forms of perimeters are given and the examination of the field of vision naturally leads to the consideration of the nature and varieties of scotomata, with the conclusions that may be drawn from their number, form, extent, and position and the inferences deducible in regard to the situation of the lesion of the optic nerve, chiasm of the tract, or primary optic centres.

More space is devoted to the consideration of prisms and lenses than is to be found in modern ophthalmological works. An account is given of Dr. Williams's lantern for testing the colour sense of those employed in signalling either on land or sea. The best chapter in the book is probably that devoted to astigmatism. The numerous arrangements of dials, letters, discs, and lines for its discovery are described and illustrated, and in addition drawings are given of Ridgeway's chromatic test for astigmatism and of Holtz's astigmometer. The thoroughness with which the formulæ used in optics are given renders this book a valuable accompaniment to any of the larger ophthalmological treatises. The reader will find a full account of the theory of Gauss and the principles involved in the schematic eyes of Donders, Listing, and Helmholtz We can recommend the work to all those who are devoting themselves to the study of the diseases of the eye.

A Manual of Medical Jurisprudence for India. By Lieutenant-Colonel J. B. GIBBONS, I.M.S. Calcutta: G. W. Allen and Co. 1904. Pp. 475. Price Rs. 12 8.

THE officers of the Indian Medical Service can to-day rely on several works on medical jurisprudence. They can consult in addition to the old but valuable treatise by Chevers the more recent works by Lyons and Barry. The latest published volume on the subject is the one now under review. The author is eminently qualified as an exponent of the subject, having been formerly police and coroner's surgeon at Calcutta and professor of medical jurisprudence at the medical college in that city. He has embodied in these pages the experience derived from eight years' service in the former office. As the result of his own personal work and of the study of the standard works on medical jurisprudence at home and abroad, Lieutenant-Colonel Gibbons has in this volume given us a worthy addition to the above existing standard works.

In his introduction the author traces briefly the successive steps by which medical jurisprudence has attained its present importance. The questions connected with medical evidence are then lucidly considered and amply set forth by various illustrations and the chapter concludes by directing attention to the facts in connexion with the drawing up of medico-legal reports. After this introduction the author enters first on the subjects in relation with death, such as its modes, its signs, the characters of the post-mortem stains, and rigor mortis. It is pointed out that whereas cardio-respiratory inhibition may simulate death yet that this condition can only last a very few minutes. According to the author's experience, the body becomes cold in India in less time than in England. The onset of rigor mortis also comes on more quickly. The importance medico legally of the curious phenomenon of cadaveric spasm is insisted upon The chapter on Putrefaction is very complete; attention is here drawn to the manner in which flies, ants, jackals, rats, and fishes mutilate the dead body, it is pointed out how in India very great variation occurs in the rate of progress and in the appearances produced in the process. Lieutenant-Colonel Gibbons mentions in this chapter the important fact that in natives the presence of food in the stomach does not justify the opinion that the patient died within six hours of taking his last meal.

The matters to be noted in the examination of the dead body come next. The author does not agree with the oft-mentioned statements in medico-legal works concerning the retention by the face of the expression which it held at the time of death. He also notes the advanced state of putrefaction that so commonly has occurred before the body has been brought into the post mortem room to be examined. In our experience this has happened in India oftener than not. A very complete description is given of the method to be followed in the making of the post-mortem examination. In the chapter on Identification, besides the signs generally described in medico-legal works, attention is drawn to those due to the religious and caste customs of the people, such as are manifested by the ears and the nose, the fastening of the coat, and the course of the sacred thread. The symptoms and the post-mortem appearances of asphyxia are then detailed and the form of capillary hæmorrhages occurring along the posterior surface of the thoracic aorta, described by Kratter as being of considerable value in this respect, is noted. The three ways of producing asphyxia—by hanging, strangulation, and throttling—are then studied in considerable detail. Thus, in asphyxia from hanging we find that the cause of loss of consciousness is discussed and attention is directed to the fact that it is due to the compression of the carotid arteries and pneumogastric nerve; the post-mortem signs, and especially those due to the mark of the rope, are detailed. As regards the diagnosis of death by hanging it is pointed out with respect to the noose mark that Casper's conclusions also hold good for India, inasmuch as no difference can be detected between the mark caused by suicidal hanging and that produced by a noose applied after death. The author here points out that in a case of alleged hanging it is well to recollect that the tissues of the neck show no sign of injury, as a rule, in cases of suicide and therefore that where injuries are found close scrutiny should be made. After death by hanging that occurring from strangulation and throttling is next fully discussed; the latter in India is a common mode of homicide and in the signs detailed attention is drawn to the fact that the crescentic cuts produced by the nails are not *often* seen in India where the custom of keeping the nails short is general. The chapter on Drowning is very complete; the post-mortem appearances are well described and here the author points out that the presence of fine lathery froth about the nose and mouth is not peculiar to death by drowning; Lieutenant-Colonel Gibbons has many times seen it in cases of opium poisoning. As regards the period during which the body will rise to the surface and float after death the author states that in his experience this will be in or within 24 hours in the hot weather and in from one to two days in the cold.

Mechanical Wounds and Injuries next claim the reader's attention. These are discussed generally and also with respect to the different parts of the body concerned, such as the skull, the spine, the neck, the chest, the abdomen, and the extremities. The important subject of Rupture of the Spleen is fully considered. We then come to the subject of Fatal Injuries; here much useful information can be found with regard to the proper answering of questions that may be put to the medical witness in court. Burns and scalds and cognate conditions are described and the reader of this work in Europe may be surprised to find the subject of Death from Cold entered into; however, should he ever visit the Punjab in the winter months he will know what cold is during the early hours of the day.

The next section is an important one on Poisoning. How important it is for the medical man can be appreciated by him when he learns that "murder by poisoning in India is three times as prevalent and suicide by poisoning many times more prevalent than in England." It is probable that murder by poisoning also is much more common in India than the recorded cases indicate. The chemical examiner to the Bengal Government at the Indian Medical Congress in 1895 clearly showed the necessity for an Act to restrict the sale of poisons and more especially of arsenic which appears to be *the* homicidal poison. The diagnosis of poisoning, the evidence of poisoning in the dead body, and the precautions to be taken in the post-mortem examination are fully stated, and the various poisons are considered.

The question of sex in all its relations and of sexual crimes is then considered and the work concludes with the subjects of Pregnancy, Infanticide, and Insanity. The author is to be congratulated on having produced an excellent treatise.

Biographic Clinics. Vol. II.: The Origin of the Ill-health of George Eliot, George Henry Lewes, Wagner, Parkman, Jane Welch Carlyle, Spencer, Whittier, Margaret Fuller Ossoli, and Nietzsche. By George M. Gould, M.D. London: Rebman, Limited. 1904. Pp. xi.–392. Price 5*s*.

The present work by Dr. Gould consists of a republication of single papers or essays, one of which, the paper on the ill-health of Wagner, originally appeared in our own columns, and may be described as an additional attempt to convert the medical profession to a belief in the author's favourite doctrine that migraine in general, as well as a large number of the maladies which afflicted the eminent persons of whom he writes, may be attributed to undetected astigmatism or to other irregular forms of ametropia and were or would be curable by the employment of proper spectacles. Dr. Gould is no doubt entirely convinced of the correctness of his assertions and he is indignant both with reviewers who have accused him of exaggeration and with those who, as he conceives, have not taken sufficient heed of his earlier publications. But even reviewers, it may be pleaded, are subject to the limitations imposed by space and time; and should not be too hardly dealt with if they are sometimes more chary of expending these than the authors with whose works they deal may consider to be fitting or necessary. The weak point of Dr. Gould's case is that some of the sufferers of whom he writes died before astigmatism was commonly recognised even by ophthalmic surgeons, and that his opinion of the causes of their ailments cannot now be regarded as other than conjectural, while with regard to some of those who died more recently the evidence actually available can scarcely be said to confirm his views. In the case of Parkman, for example, Dr. Gould represents him as having entirely neglected study while at Harvard but does not explain how it happened that at the age of 21 years he graduated there with high rank; and in the case of Nietzsche he would have us believe that an astigmatism sufficient to produce serious symptoms was overlooked so lately as in 1899 or 1900 (the dates are somewhat vague) by no less an authority than Professor Alfred Graefe of Halle. As a matter of fact, indeed, it is an essential part of Dr. Gould's argument that English and German "oculists," as he calls them, habitually ignore or neglect not only astigmatism but also, generally speaking, all defects or inequalities of refraction which are slight or moderate in degree and which, he contends, are more frequently productive of serious symptoms than higher grades of the same conditions This latter conclusion appears to us to be contrary both to common sense and to experience; and the suggestion that ocular defects can only be recognised and dealt with in America is one that seems hardly to call for serious consideration.

It is, of course, perfectly well known that errors and inequalities of refraction are liable to produce headaches and other discomforts, including incapacity for sustained near work, but we think it is impossible to assign to these causes more than a very small part of the influence which Dr. Gould claims for them. He tells us that "the doing something while sitting means 'eyestrain' in *at least 25 per cent. of the doers*," and a few sentences before that the effects of "eyestrain" may be "awful," the "rights of the irritated brain being ruthlessly trampled upon by the most cruel overuse and abuse." With great submission to an American experience which is repeatedly described as covering "thousands" and sometimes "millions" of cases of this kind, we feel bound to say that, tested by the opportunities of this country, such assertions not only exaggerate the facts, but carry exaggeration to a limit at which it is either rendered harmless by its absurdity or is even calculated to produce a reaction possibly tending towards neglect. The one possible use of Dr. Gould's book will be to render ophthalmic surgeons careful to afford no justification for his strictures, and to increase the care of physicians in requiring complete investigation of the refraction of neurotic patients; but it is not likely, we think, to make many converts to his views. Among other grievous faults it is disfigured by an almost ferocious violence of language such as should have no place in a scientific discussion. The action or alleged inaction of "German and English oculists" is repeatedly described as "criminal," and Dr. Gould is not content with his endeavours to explain all Mrs. Carlyle's troubles by astigmatism but quite superfluously engages in the unsavoury contest which has recently raged over her life and correspondence and brings to it such words and sentences as "asinine," "atrocity," the "loathsome and infamous deed of a cowardly bungler," and so on *ad nauseam*. He has yet to learn that unmeasured language adds no force to argument and that mere abuse is eminently distasteful to gentlemen.

LIBRARY TABLE.

Martin's Up-to-date Tables of Imperial, Metric, Indian, and Colonial Weights and Measures. Compiled and written by ALFRED J. MARTIN, Fellow of the Surveyors' Institution, England. 1904 Pp. 255. Price 2*s.* 6*d.* *Martin's Up-to-date Beginners' Table book.* Pp. 48. Price 1*d.* London: T. Fisher Unwin.—The main object of the larger book of tables seems to be to encourage by comparison and argument the use of the decimal metric system of weights and measures and is more likely to appeal to adults with matured judgment than to school children. The two books are certainly full of useful tables and information of a kind that it is often difficult to get hold of quickly when wanted but there are a few things that require correction. In the penny introductory book, which is stated on the cover to be "for schools and home teaching," we think that it would have been better to omit the arguments in favour of the metric system and we hardly think that the pupil should be told that "all weights and measures not appearing in the following tables are purposely omitted to prevent a pupil's mind from being crammed with a lot of nonsense," and that "it is not only waste of time but harmful to teach *obsolete* tables of bread, butter, coal, wood, &c., put in most table-books." If a master is bound to teach these tables it might lead to rebellion and argument on the part of the pupil and to subversion of discipline. The rule for changing a recurring decimal fraction to a vulgar fraction given on p. 21 of the little book is not clear to us and we think that the terms "numerator" and "denominator" have become mixed. In the large book under "Measures of Temperature" the name of Celsius has been printed "Celius." One of the formulæ for converting degrees of temperature from one scale to another is given as $R=\frac{4(F-32)}{8}$. Here 8 has evidently been printed in mistake for 9. It is interesting in this connexion to note that the second reading of the Weights and Measures (Metric System) Bill was moved by Lord Belhaven in the House of Lords on Feb. 23rd. The object of the Bill is to render compulsory the use of the metric system of weights and measures in this country. This Bill was supported by Lord Kelvin who contended that the decimal system worked out by the French philosophers originated in England. In a letter dated Nov. 14th, 1783, James Watt laid down a plan which was in all respects the system adopted by the French philosophers seven years later. A writer in the *Daily News* of March 10th, 1904, claims that an Englishman, Sir John Riggs Miller, M.P., largely influenced the French in 1790 in starting the practical adoption of the metric system in France. Lord Belhaven stated that the adoption of the metric system would be of great advantage to our export trade. This was especially the case with the drug trade. It was given in evidence before the committee of 1895 that at the beginning of the nineteenth century the drug trade of the world was confined to London; at the end of the century London still retained 70 per cent. of this trade but was now fast losing the command, many of the drugs being sent to Amsterdam and Havre because people did not like to weigh and to pay for them by English measures. The South American Republics now went to Paris for their drugs because the metric system was used there. The Marquess of Lansdowne instanced the danger of getting English medical prescriptions made up on the continent, some pills being made for a friend of his as large as marbles in consequence of the ignorance of the druggist's assistant of English weights and measures. On April 15th, Mr. Bousfield, M.P. for North Hackney, moved the second reading of his Weights and Measures Bill in the House of Commons and tried unsuccessfully to introduce an instalment of the metric system and to abolish troy weight and apothecaries' weight. Particulars of this Bill will be found in THE LANCET of April 23rd, p. 1169, under "Parliamentary Intelligence." At p. 154 of his tables Mr. Martin gives a list of proposed reforms, one being the abolition of the old apothecaries' weight, and after two years the discontinuance of avoirdupois denominations in the Pharmacopœia and the issue of metric weights and measures to medical men, druggists, and others. Another reform proposed is the abolition of the apothecaries' fluid measures. The metric system of weights and measures is very useful and simple for many purposes but we have known well-educated people who have studied decimals say after doing a sum, "Yes, the figures are all there, but where am I to put the dot?" If the dot is put in the wrong place in medical prescriptions it may lead to serious trouble. To some minds the Latin and Greek prefixes of milli-, centi-, deci-, deka-, hekto-, kilo-, are confusing but these terms need not always be adopted. The duodecimal opponents of the decimal system complain that ten is not divisible by three without a remainder. This is particularly brought home where three articles are sold for 25 centimes, and a person only wants to buy one or two. We have observed that those Englishmen who have become thoroughly acquainted with the metric system of money and measures abroad are in favour of its adoption at home. Those who have not had that experience rather dread the innovation because it will give them a lot of trouble to learn new tables although they are willing to admit the advantages of the decimal system. In the engineering, electrical, and other technical trades and scientific circles in this country decimal metric weights and measurements are used every day and have become almost indispensable. The fact that the decimal metric system has become so extensively used by all the highly civilised nations with the exception of Russia and Great Britain is a very powerful argument in its favour. We feel that if the weights and measures of the decimal metric system are made compulsory in this country, a decimal system of coinage must be adopted simultaneously. Otherwise the full advantages of the system will not be apparent and there might even be confusion in trades dealing in dozens and grosses at certain prices.

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. Vol. XXXVIII., Part III. April, 1904. London: Charles Griffin and Co., Limited. Price 6*s.*—The contents of this number of the journal are: 1. A Study of the Astragalus, by R. B. Seymour Sewell, B.A., with four plates. Mr. Sewell has examined and compared upwards of 1000 specimens of this bone obtained from the tombs of the predynastic Nagadah race and from the tombs of Egyptians, the dates of which range from the fifth dynasty to the Ptolemaic and Roman periods. He obtained a length-breadth index by dividing the greatest breadth + 100 by the greatest length; the average was found to be 78 but there were considerable variations. Diagrams show the different types of curvature in the trochlear facet. 2. Observations on Traction Epiphyses, by F. G. Parsons, F.R.C.S. Eng., with 13 illustrations. 3. John Grattan's Craniometer and Craniometric Methods, by Johnson Symington, M.D. Edin., with two plates. 4. On the Presence and Significance of the Superior Commissure throughout the Vertebrata, by John Cameron, M.B. Edin., with two plates. Dr. Cameron finds the superior commissure a constant and well-marked structure in birds, the fibres arising from the cells of the ganglia habenulæ and decussating. In the adult human brain one lateral half of the pineal gland is supplied by fibres from the ganglion habenulæ of the opposite side.

Hence the human pineal gland is probably a bilaterally developed structure possessing a bilateral nerve-supply. 5. A Method of Demonstrating Tracings to Large Audiences, by Walter Colquhoun, M.B. Glasg. 6. A Comparative Study of the Grey and White Matter of the Motor-cell Groups and of the Spinal Accessory Nerve in the Spinal Cord of the Porpoise (Phocœna communis), with five plates, by David Hepburn, M.D. Edin., and David Waterston, M.D. Edin. 7. Observations upon the Distribution and Structure of Hæmolymph Glands in Mammalia and Aves, including a Preliminary Note on Thymus, by Thomas Lewis. 8 Lectures on the Early Stages in the Development of Mammalian Ova and on the Differentiation of the Placenta in Different Groups of Mammals, by Arthur Robinson, M D. Edin., with two plates. 9 The Germ Cells, Part I. continued, by John Beard, D.Sc.; Sect. xiv., Primary and Secondary Germ Cells.

The Quarterly Journal of Microscopical Science. Edited by E RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R S, W. F. R WELDON, F.R S., and SYDNEY J. HICKSON, F.R.S. With Lithographic Plates and Engravings on Wood. London: J. and A. Churchill. New Series, No. 188. 1904. Pp. 145. Price 10s—This number contains the following memoirs: 1. Edwin S. Goodrich, M A., on the Dermal Fin Rays of Fishes, Living and Extinct, with seven plates. Mr. Goodrich finds that in all the fins of true pisces there are present dermal rays of mesoblastic origin, the dermotrichiæ. In the elasmobranchii and holocephali and probably also in the acanthodii and ichthyotomi these rays are unjointed, occasionally branched and composed of a fibrous substance of horny consistence without bone cells. These he proposes to term ceratotrichia. All living teleostomes are provided with small horny unjointed rays at the edge of their fins to which the name actinotrichia has been given. The teleostomes are further provided with jointed and branched bony dermal rays developed outside the actinotrichia. They closely resemble the body scales, from which they are probably derived, and Mr. Sedgwick proposes to call them lepidotrichia. In the dipnoi (lepidosiren, protopterus, and ceratodus) are found jointed dermal rays of bony substance containing bone cells. To these the name of camptotrichia is provisionally given. The camptotrichia of the dipnoi represent the lepidotrichia of the teleostomes and the lepidotrichia are probably derived from modified scales. 2 E Ray Lankester, F.R S.: The Structure and, Classification of the Arthropoda. This memoir is a reprint of the articles Arthropoda and Arachnida, which were published four years ago in the widely advertised tenth edition of the Encyclopædia Britannica but which Mr. Lankester complains have been overlooked by recent writers. 3. Professor Marcus Hartog: Some Problems of Reproduction. The first part of this article is occupied with the subject of multiple fission and embryonic enzymes; the second is an essay on fertilisation, in which the author gives a very interesting account of recent views of the nature of this process.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 29, 1826.

REVIEW.[1]

Transactions of the Medical and Physical Society of Calcutta. Volume the First. 8vo. pp. 406. Thacker, Calcutta, and Parbury and Co., London, 1825.

To the oriental nations we owe the introduction of many simples into medicine, which were unknown to the Greeks and Romans, such as manna, senna, tamarinds, and rhubarb, besides musk, nutmegs, cloves, &c.; and in modern times, the mandàr, croton oil, &c. Hence it is not improbable, that many valuable remedies may yet be culled from the Materia Medica of the East; but if no accessions of value be derivable from that source, a vast store of knowledge, important equally to physiology and pathology, may be collected and rendered subservient to the healing art. That much may be done, is proved by the present volume of transactions, which, although the Society has been so recently established, contains many papers of sterling value, of these we shall now proceed to give some account. The first is an elaborate dissertation on "*Kushta*, or Leprosy, as known to the Hindus," by H. H. Wilson, Esq. The author of the present paper first takes a general view of the Hindu notions of leprosy, rightly judging that they might form a serviceable and interesting introduction to future and more scientific inquiries. "The advanced state of medical knowledge in Europe," he remarks, "is a sufficient security that the errors of these guides, imperfect as they undoubtedly are, will not lead us astray, whilst, from their long experience and accumulated observation, it is possible that some hints may be derived, which may lead us to an improved knowledge and classification, if not to a more successful treatment of the disease." From the systems of Hindu medicine,* therefore, (and it appears they are never satisfied with less than a system,) the author proceeds to specify the causes, symptoms, prognosis, and diagnosis, classification, and treatment of leprosy, a disease (according to these authorities) of the constitution, first disorganizing the integuments, but proceeding to destroy the solid parts and dismember the body.

According to Hindu writers, the causes of leprosy are disorders of the primæ viæ, however induced; hereditary disposition; contagion, and "political or popular superstition." Under the first head they reckon the taking of things which do not assimilate, as milk and fish, and viscous and indigestible foods. Exposure to fatigue or heat, after a full meal. Drinking water or walking while heated. Excessive bodily exertion or mental excitement. The use of new rice, curds, fish, and of salt and acid viands; of pulse, radishes, sesamum, milk, and treacle. Also sexual intercourse, and sleeping under a loaded stomach.

They assert that the blood and serum are affected by the disease, and that it may be thus communicated to the fœtus in utero. They declare that it may be communicated by contact, by breathing the same air, by eating together, by sitting on the same seat, or by wearing the clothes and ornaments, or using the perfumes of an affected person.

Lastly, to abuse Brahmins, or to hold in contempt spiritual preceptors, with many similar offences are superstitiously supposed to generate this loathsome affection.

It is probable that in warm countries rancid foods, or proper ones if devoured in excessive quantities, may be causes of this disease. Dr. Henderson makes the former one of the causes of elephantiasis in Norway, and Good, unwholesome diet of the Spanish and Italian varieties of that disease. Dr. T. Heberden also states that in Madeira, fish, melons, cucumbers, young garden beans, or mulberries, taken at the same meal with butter, cheese, or any preparation of milk, are supposed to produce it, and are therefore religiously avoided. Upon the whole, there is not much of novelty in the first set of Hindu causes.

---

[1] Only a portion of this review has been transcribed. The whole occupies nearly eight pages of THE LANCET. 18 sorts of leprosy are enumerated in detail.

* The authorities which the author consulted, are the following:—The *Chikitsá*, or practical chapter of CHARAKA, which includes the *Nidan*, or pathology; the practical chapter of SUSRUTA; the *Chikitsá* and Nidan of BAGRHATTA; the Chikitsá of CHAKRADATTA and BANGA SENA; the *Nidan* of MADHAVA; the practical section of the *Rasa Ratnakar*, and the chapter of the *Bháva Praxás*, which comprehends all the branches of the subject. The classification of CHARAKA and SUSRUTA is uniformly adhered to.

ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of Fellows of the College practising in Birmingham and the Midland counties was held at the Medical Institute, Birmingham, on April 21st, Mr. Frank Marsh being in the chair. The following motion proposed by Mr. George Heaton, seconded by Mr. John W. Taylor, and supported by Mr. Jordan Lloyd and others was unanimously adopted:—

> That this meeting of Fellows of the Royal College of Surgeons of England practising in Birmingham and the Midland counties is of opinion that the provincial Fellows are at present inadequately represented on the Council of the College and pledges itself to support the candidature of Mr. Gilbert Barling at the forthcoming election.

LONDON: SATURDAY, APRIL 30, 1904.

Small-pox and Vagrancy.

THE report of Mr. H. E. ARMSTRONG, medical officer of health of Newcastle-upon-Tyne, upon small-pox in relation to vagrancy is primarily a document issued for the information of the sanitary committee of the Newcastle corporation with reference to the dissemination of a particular disease by tramps. At the same time, however, its contents are fit matter for the consideration of all sanitary authorities throughout the United Kingdom and of the public whom it is their duty to safeguard, not merely because small-pox is a deadly and infectious disease but because all ought to realise that the tramp is a source of danger to the moral and the physical health of the community. In connexion with the present outbreak of small-pox and in order to ascertain the experience and the opinions of competent authorities upon its relation to vagrancy Mr. ARMSTRONG addressed a circular containing ten questions to the medical officers of health of 205 urban localities having populations of 20,000 and upwards. He has received and tabulated replies from 126 districts, 111 of which have suffered from small-pox during the recent epidemic, and of these 75 owed the introduction of the disease to tramps. This is a formidable proportion, whether we regard it as constituting over 50 per cent. of the districts returned as infected or as more than 25 per cent. of the whole. It is no trifling matter that one quarter of the principal cities, boroughs, and urban districts of England and Wales should have had to acknowledge the presence of small-pox with the expense and anxiety accompanying such a visitation and that this should be due to the insanitary and reckless habits of a worthless section of the community. The facts embodied in Mr. ARMSTRONG'S report and in similar collections of statistics surely should induce sanitary and other authorities to minimise the evil effects of the habits referred to and at the same time to lessen the evils inseparable from vagrancy by discouraging its existence. This can best and most justly be done by depriving it of its principal attractions. To wander at will without question and to be as dirty as he pleases are conditions of life essential to its enjoyment by the tramp; if they were made impossible for him he would almost cease to exist. Moreover, after living among vagrants in Germany, America, and England, Mr. FLYNT, the author of "Tramping with Tramps," declares that the British variety is far dirtier and more ragged than his Teutonic or his Transatlantic cousin. He appears also to be restrained less by law.

Among the questions asked by the medical officer of health of Newcastle-upon-Tyne which introduce or suggest the general topic of vagrancy is No. 7: "What means in relation to the spread of small-pox have you adopted to secure information as to vagrants visiting common lodging-houses? Have you put in force the provisions of Section 83 of the Public Health Act, 1875?" We find from the replies to this that in 56 out of 126 districts systematic inspection of common lodging-houses is relied upon and that in 37 only is Section 83 made use of. This provision of the Public Health Act is useful so far as it goes but its limited application is typical of our policy in such matters. It orders that the keeper of a common lodging-house in which beggars or vagrants are received shall from time to time make a report as to who has resorted to the house, with the reservation that this shall be done "if required in writing by the local authority." The discretion allowed to local bodies in such matters and the resulting variety in the methods adopted are shown from the answers to other questions besides the one referred to. Whether the tramp be regarded as a social or as a sanitary evil it seems highly desirable that a uniform manner of treating him should be obligatory throughout the kingdom. At present that locality profits the police and sanitary officers of which harass and restrain the wanderer, for it gets less than its share of vagrants and its laxer neighbours suffer in proportion to their laxity. The community at large, however, derives no benefit, for the attractions of vagrancy remain for those who know where to seek them. Other points with regard to which different practices prevail in different localities and to which Mr. ARMSTRONG'S report draws attention are the medical examination of tramps presenting themselves for admission to casual wards and the efforts made to impose revaccination upon them. Uniformity in the former case and the power to employ compulsion in the latter would seem to be desirable and just when we consider that these are persons who, whether they wander to seek work or in order to avoid the necessity of performing it, when they arrive in a district become a burden upon it with little prospect or with no intention of being anything else.

At the same time the problem of the vagrant is not one which can be dealt with easily or which can be solved by the enforcing of sanitary laws alone. The tramp is a moral and social evil as well as a danger to health. Drink has often been the original cause of his downfall and it remains as frequently a bar to his possible reformation. He may be vaccinated or cleansed when he patronises a casual ward and one of Mr. ARMSTRONG'S correspondents suggests that every common lodging house should have a bath to be used compulsorily and an isolation room for suspicious cases of illness. For several months of the year, however, the casual ward and the common lodging-house are the luxuries rather than the necessities of tramp life. The season is now beginning when those who have been spending the winter nights under cover in towns will find the hedge-row or the unwatched shed or outhouse sufficient in any locality where irksome conditions are attached to the use of more substantial sleeping apartments. "Sleeping out" may be punishable when those who indulge in it are brought before the magistrate but we are all familiar with the protests raised by so-called humanitarians when "sleeping out" is "punished as a crime" The carefully inspected common lodging-house, the Salvation Army shelter, cheap food, and the indiscriminate charity of rich and poor are sometimes welcome aids to the deserving worker in temporary difficulties but they combine to render the life of the tramp not only possible but pleasant and attractive. They enable the idle to live either by mendicancy or by crime or by both without any need to work and the example of men and women leading indolent, self-indulgent lives without responsibility or restraint is a constant temptation to others to adopt the same course. To control the beggar and the vagrant so as to prevent him from being by his example and contact a danger to his more industrious neighbours is no easy task for a country to undertake; to make a labouring man of the confirmed wastrel is still more difficult and in many cases may be found impossible. At present in the United Kingdom jails and the casual wards of workhouses are practically the only means provided for teaching him; the policeman eyes him with suspicion and enforces a Vagrancy Act passed in 1824 and the medical officer of health watches him with apprehension but cannot forcibly control his liberty to spread disease even when he is believed to have been in contact with it. The Salvation Army and other private agencies have made experiments with labour colonies and similar institutions. For organised State intervention, however, specifically directed against vagrancy we must seek examples abroad. Mr. ARMSTRONG refers to the colony at Merxplas in Belgium and to four others in that country for undesirables who are not criminals, and there are examples and experiments elsewhere. The literature on the subject published in England alone is not inconsiderable and the recommendations which have been made are numerous and in many cases of a practical nature. Legislative interference in such matters is, however, not easy to rouse and, as has been pointed out above, it usually takes the form of conferring powers upon local authorities and private individuals which they may exercise or not as they please. This is a characteristic of the private Bill now before Parliament to promote the establishment of labour colonies and to enable judges and magistrates to order vagrants to be detained in them. Meanwhile, the army of tramps does not diminish; indeed, it apparently doubled itself recently in a period of ten years and is probably still on the increase. A pedlar poet quoted by Mr. ARMSTRONG has written of the wanderer's existence—

> "If such a life as this I live
>   Offend some tender, high-strung soul,
> Then I must pray him to forgive
>   A blame of which I bear the whole."

But we may point out that the offence is to the soul not of the highly strung and tender but of those who have at heart the moral and physical welfare of the people and that the blame is not to be borne wholly by the tramp but must be shared by the system which permits, and, indeed, renders easy, his existence.

◆

Feeding in Relation to the Health of the Young.

THE Victoria University of Manchester is unquestionably rendering a valuable public service in printing the little pamphlet which has recently been sent to us and which represents a report of a lecture delivered by Dr. JAMES NIVEN, the medical officer of health of Manchester, on the subject of Feeding in Relation to the Health of the Young. We gather that this is one of a series of lectures bearing on the general subject of food and drink in relation to disease. In Manchester, as in other large centres of population, the signs of the physical degeneration of the people would appear to be so obvious that it has become necessary for the custodians of the public health to take official cognisance of a state of affairs which, if allowed to drift, might have serious industrial and economic results. It is a curious fact that although it is considered by many medical men that there is a progressive deterioration in the physique of the poorer classes in our towns there are no trustworthy anthropometrical statistics on a sufficiently large scale to prove that this widespread belief is true. This state of affairs, as we indicated in a leading article in THE LANCET of April 9th, p. 1003, will probably in the near future be rectified by systematic observations of height, weight, and general physical condition, being taken in the elementary schools. Dr. NIVEN has not accepted the progressive physical degeneration of the urban population as a proposition needing no demonstration, but has attempted to prove his point by relying on statistics of mortality. He contends that there is a close relationship between the capacity of wages to obtain food and the physical condition of the people. This, no doubt, is a perfectly justifiable conclusion, as also is the deduction that inadequate and improper dieting during the periods of infancy and childhood is the chief factor in the determination of physical inferiority in later years. In his lecture Dr. NIVEN makes certain practical suggestions for improving the present unsatisfactory condition of affairs. Among the more important of these suggestions may be included the following: that teachers should be trained to look after the physical condition as well as after the mental instruction of their scholars, that there should be legislation to enable the educational authority to enforce the provision of sufficient food and the maintenance of cleanliness in school children by parents, that the educational authority should be empowered to obtain from the rates sufficient provision for the free feeding of children under certain definite conditions, that in all schools a kitchen should be provided for instruction in the elements of cooking, and finally that the poorer population generally should be instructed as to the diet requisite and the means by which it may be most cheaply obtained. This latter point is a most important one, for in the economical expenditure of wages on food—and by economical we mean economical in both a physiological and a pecuniary sense—there is still a great deal to be learnt not only by parents but by others who are supposed to be familiar with the principles of dietetics. As a matter of fact, growing children require a much larger proportion of nitrogenous food than do grown-up persons, but among the poorer classes it is almost invariably the case that relatively they receive a very much smaller quantity, chiefly for the reason that nearly all forms of food of this kind are more expensive than the less essential but commoner varieties of carbohydrates. With a little ingenuity in cooking, two very cheap and valuable varieties of food—namely, pea flour and cotton-seed oil—might be largely employed for providing the poor with palatable and genuinely nutritious meals. The value of these foods in the feeding of cattle is well known but both of them are neglected in their application to the feeding of human beings. Although we have only mentioned a few of the many excellent points which Dr. NIVEN brings out in his lecture we have probably said enough to indicate that it deserves to be read by all those who are concerned with educational and hygienic questions.

◆

A Bolt from the Blue.

OUR esteemed contemporary the *St. James's Gazette* has suddenly discovered, or at least has suddenly announced, that the medical profession is in a parlous state and that its "ineptitude" is such as to constitute "a national danger." It seems that while we, its humble members, were on the whole rather well-satisfied with ourselves, thinking that the more original-minded of our number had made discoveries or had introduced improvements which were calculated greatly to diminish the ravages of disease, and that the immense majority were at the very least doing their best to render these discoveries and improvements available for the service of the public, we have, after all, been self-deceivers to a pitiable extent. The *St. James's Gazette*, supported by no less an authority than that of an unnamed "old resident surgeon at a famous London Hospital," one, moreover, who has achieved the exceptional distinction of being not only "M.D." but also "B.Sc. (Lond.), M.R.C.S. (Eng.), and L R C.P.," has torn away the veil behind which our weaknesses were concealed and has displayed us as we are to a scornful and horror-stricken world. It appears that there are "degrees which are legal registrable qualifications, but which would not entitle the holder to be considered in a senior student or junior house appointment at a good London hospital," and also that "anyone who has done (*sic*) a resident appointment at a big hospital will tell you of the huge blunders made by town and country practitioners alike, men of poor qualifications and no experience, who will go on making the same mistakes and missing the same vital points simply because there is no one to check them." Following these cheerful and lucid accounts of our deficiencies we have a gruesome history of a man with hæmorrhagic small-pox who was brought by his medical attendant (surely at least a benevolent and kindly one) 50 miles in a third-class carriage in order that he might reach a hospital where he could be operated upon for supposed stone in the kidney, and of another man who was told that he was "dying of consumption" and must not marry and who nevertheless got well, a "chance consultation with another man," possibly the narrator, having brought to light the fact that the supposed consumption was "a sort of muscular rheumatism." As a protection against the dangers likely to arise from the employment of incapable practitioners the public are advised to study the Medical Directory, which "gives shortly a man's qualifications, his appointments, and so forth," by which course not only would "the man in the street have less cause for complaint, but there would arise by competition a necessity for more skill and experience among the rank and file of the medical profession." Even this desirable consequence is scarcely held forth as a certainty, because the correspondent adds that "the public does not see any difference between A.B., late H.P., and C.D., L S.A. They are both equally doctors." "Late H.P." is good if, as we suppose, the mysterious initials mean "house physician." We cannot suggest any other interpretation of them, but an earlier portion of the letter described the writer as an "old" (? late) "resident" (? house) *surgeon*. It is gratifying to note that he holds the kindred office in even higher esteem than that which he would no doubt claim to have filled with distinction to himself and with advantage to his patients.

It is really pitiable that a respectable newspaper can be beguiled into giving currency to such flatulent rubbish as this. As a matter of course the medical profession, like every other, includes men of various kinds and degrees of capacity. Even the wisest of them are not infallible and only the most foolish of them think themselves so. The somewhat ungrammatical correspondent of our contemporary falls, we greatly fear, within the latter category. There are very few men of real professional learning and experience who have not encountered from time to time the "cocksure" youngster fresh from the schools or the hospital and who have not been amused by his kindly methods of dealing with their supposed deficiencies. But such youngsters, as a rule, are not eager to rush into print or to accomplish the feat known in homely phrase as "the fouling of their own nest." Generally they are more inclined to be magnanimous and to conceal the fancied errors which they plume themselves upon having detected. To write after the fashion of the correspondent of the *St. James's Gazette* is to display a profundity of unwisdom which only a very few persons can ever hope to reach. If he were to publish his name and so to seek "bold advertisement" of the skill which had enabled him to proclaim the errors of others his position would at least be intelligible, and non-medical persons of his own mental calibre are sufficiently numerous to confer upon such an enterprise some reasonable hope of success. By anonymity he cuts his own throat as well as the throats of his neighbours. When next he gives good advice to a patient he must expect to be told, on the authority of the *St. James's Gazette*, that medical men generally are incompetent and ignorant persons and that he himself is probably one of the majority. It will be of small avail for him to have an extract from the Medical Directory in his pocket-book, or even to display convincing evidence of an "old" H.P.-ship. The rule is likely to make more impression upon the patient than the exception, and even "old H.P.s," being human, must admit their liability to occasional error.

But, after all, fools have their uses and the curious effervescence of this particular example of the genus may possibly be rendered subservient to purposes of utility. It is probably true that some members of the medical profession, we believe a very small minority, can hardly be described as fit for the discharge of the duties which they undertake, and it is a question worthy of serious consideration whether for the future such persons should not, and might not, be altogether excluded from its ranks. We believe them to be mainly or entirely recruited from those who at most hospitals are known to the authorities as "chronic" students—men who from the first take but slender interest in the facts and principles which it is their duty to master and who either from idleness or incapacity are late in completing each of the stages of a student's career or who fail in successive examinations or in successive control and that the Board of Education lays down excellent rules. But these rules are in many instances disregarded and the Board of Education seems to have no machinery for enforcing its recommendations. Dr. Walford gives various instances in which ventilation was found defective and where the only heating apparatus was one which was strictly forbidden by the Board of Education—namely, a cast-iron stove with a flue-pipe running through the wall. He further quotes an instance on the authority of Dr. J. Kerr, formerly medical officer to the Bradford School Board, in which the amount of carbon dioxide in a Bradford school was found to be 31 volumes per 10,000. Besides ventilation Dr. Walford touched upon many other points of school hygiene, such as the provision of separate seats or desks and the spread of infection by means of school attendance, and concluded by referring to the necessity for medical inspection of schools and scholars. He mentioned in this connexion the recommendation of the recent Royal Commission on Physical Training (Scotland) to the effect that it is desirable that all schools should be under medical inspection. How this is to be carried out is a question by no means easy to answer but primarily the sanitary authorities, who after May 1st will be the education authorities too, must be responsible for medical inspection. Ratepayers are only too painfully aware of the expense of education but a little more spent upon medical supervision of the schools and scholars would result in a saving to the ratepayers by the lessening of epidemics of such diseases as diphtheria and scarlet fever.

"NEURASTHENIA."

Invented by Beard of America in the "sixties" to describe and to include a class of nervous affections more common in America than elsewhere, the term "neurasthenia" has been used with great elasticity since then to cover a multitude of obscure nervous affections of the most varied and opposing characters, to the great confusion of exact diagnosis and of scientific treatment. A process of elimination has, however, been going on during the past decade and much has been done to clear up and to define more precisely the essential characters of neurasthenia. In the *Boston Medical and Surgical Journal* of March 31st Professor Charles Dana deals with the important differential characters of this condition. While neurasthenia is, says Professor Dana, a psychosis or morbid condition of the cerebral nervous system it is different from a large number of psychical states which, though not acute or severe enough to constitute insanity, show a definite kinship to insanity. These cases come to the general practitioner or to the neurologist by whom they are put down commonly as some form of neurasthenia, hysteria, or "degeneration." "It is my contention," adds Professor Dana, "that a large number of these so-called neurasthenics and all the hysterics should be classed as prodromal stages or abortive types—a shadowy imitation—of the greater psychosis insanity. For in these cases it is the morbid mind which dominates the situation, not a weak eye-muscle, a poor stomach, a heavy womb, uric acid, arterio-sclerosis, or even an exhausted motor nerve cell." The psychical centres of the brain are the primary seat of the disorder, but the body may also be at fault. Many of these neurasthenic conditions are understudies as it were of the graver forms of mental aberration. There are, broadly speaking, says Professor Dana, five classes of insanity which represent varying degrees of departure from mental health and stability of brain (excluding idiocy, imbecility, and the organic dementia of syphilis, epilepsy, and cerebral softening). Representing the normal condition of the ego by a horizontal line the mental departures from this line (degrees of alienation) are in the following order of increasing magnitude—viz., dementia præcox, paranoia, maniacal-depressive insanity, melancholia, phrenasthenic psychoses, and toxic and exhaustion psychoses. The insanity of puberty and adolescence, which occurs before the age of 30 years and very often before 20, sometimes may come on quietly and insidiously with a long period of pseudo-neurasthenia. Paranoia is a form of grave and progressive mental disorder which comes on after adolescence and has a tendency to a cyclical course in which there are at first depression, moodiness, suspicion, egotism, and a sense of being badly treated; then follow systematised delusions and sometimes active explosions of excitement. The course is long but there is very little tendency to dementia, for though the degree of alienation is great the organic deterioration of the brain is almost inappreciable. The condition known as maniacal-depressive insanity is harder to recognise. We see much melancholia but true acute mania is rare. But there is, adds Professor Dana, a depressive insanity which begins early in life, often develops from slight causes, and recurs again and again with slight tendency to dementia. The chronic melancholia of middle and later life is often heralded by a "history of nervous prostration or of obscure nervous attacks when in the twenties or later," which have occasionally recurred. It can readily be understood that what is a pure psychosis, as is maniacal-depressive insanity in youth, may easily be made a chronic one by the complications and degenerative changes of later life. The late development of a psychosis such as this suggests that the constitutional taint underlying it is dying out, since violent mental confusion and tendencies to dementia are not seen in the pure forms of maniacal-depressive insanity in youth. The phrenasthenic psychoses form a "degenerative" group. It includes the mental and moral perversions, hysterias, phobias, aboulias, as well as morbid impulses and imperative ideas, and the many forms of dipsomania. With all patients of this class there is a tendency to "psychical storms or explosions" as in dipsomania, hysteria, and impulsive acts, or to fixity of morbid ideas, such as obsessions of fear, doubt, superstition, and the like. These patients are also neurasthenic on the somatic side. "I have been watching for a case of neurasthenia due to excessive physical work alone," says Professor Dana, "but I have never seen it." It does not occur—for example, as the result of long and hard athletic work, nor in bicycle races, or six-day pedestrians, or in firemen and stokers. "It is also the psyche that has to be hit in order to get a neurasthenia." Neurasthenia, strictly speaking, very rarely occurs under twenty. What we see then is the pseudo-neurasthenia of dementia præcox, or dementia præcox itself, or slight attacks of recurrent maniacal-depressive insanity, or the initial symptoms of a developing phrenasthenia. The depressive and anxious types of neurasthenia occurring after the age of 40 or 45 years are usually mild forms of the involutional melancholia of middle age, while so-called congenital neurasthenia is usually a phrenasthenia, a dementia præcox, or a paranoia. Cutting out the foregoing, concludes Professor Dana, one has cut away about one-half of the great national malady attributed to America.

INFANT FEEDING IN FRANCE.

In France the artificial feeding of infants has during recent years to a considerable extent displaced the time-honoured system of wet-nursing. Establishments known as "gouttes de lait" have arisen in various places. In these institutions, which are under medical supervision, sterilised milk is supplied to poor parents gratuitously or at a reduced rate. It is not pretended, of course, that any substitute of equal value for the mother's milk has been found. Nevertheless the feeding bottle is considered to be more wholesome and more merciful than a foster-mother and its effect on the health of the infant appears to have been distinctly beneficial. At such a "goutte" in Rouen 128 children were supplied, 46 of these being healthy when entered and 82 suffering from gastro-enteritis. Among the former there were four deaths, two from gastro-enteritis, and among the latter 22 deaths, of which seven were due to this disease. At Amiens prior to 1900 the mortality from gastro-enteritis varied between 292 and 196 cases. In 1900 a "goutte" was opened and the death-rate from this cause fell to 168 in 1901 and 100 in 1902. In the Montmartre district of Paris there were not more than 47 deaths among 384 infants taken to the "goutte." These figures, if not definitely conclusive, at least suggest an increased security of infant life under the new system. In estimating its effect allowance must necessarily be made for occasional errors due to ignorance or carelessness on the part of mothers or nurses. After more prolonged experience the statistical records of these institutions, already far from discouraging, may be expected to assume an aspect even more favourable than at present. Artificial feeding, when thus carefully carried out, possesses an obvious advantage over foster-parentage in the fact that it insures, or should insure, the continued supervision of a mother, while it also obviates the danger of constitutional contamination by the wet-nurse. It is the plan which has always found most favour in this country where the maternal source of supply has not been available. Its employment in the like case is further justified in France by the objection hitherto entertained there to the use of milk-food preparations which are unfortunately still too freely used in the British nursery.

ANTIVACCINATIONIST GUARDIANS AND THEIR VACCINATION OFFICERS.

A MAJORITY of the guardians of the poor in the Wandsworth and Clapham union hold "antivaccinationist" views and the methods which they adopt in order to avoid the fulfilment of their public duties in respect of vaccination are consistent with their opinions. These methods are likely to prove expensive to the ratepayers of Wandsworth and Clapham who will have to pay the costs in two actions brought against their board of guardians by two vaccination officers which were recently tried together by Mr. Justice Channell sitting without a jury. The actions were brought by the vaccination officers to recover the amount of two solicitors' bills of costs incurred in the prosecution of offenders against the Vaccination Acts. Upon a past occasion the antivaccinationist majority on the board had resisted the payment of solicitors' costs for this purpose and one of the vaccination officers had in consequence ceased to prosecute offenders. As a result of this the Local Government Board, which, of course, has power to dismiss him from his office, had exacted from him an undertaking to take proceedings in future. He had accordingly resumed the fulfilment of his duties but the opposition of the antivaccinationist guardians had continued, one of these gentlemen saying to him: "If you dare to take proceedings we will employ Mr. Schultess Young to fight you." This threat, intimating that legal aid would be at the disposal of all defendents, coupled with the fact that the barrister named was, in fact, employed in a large number of cases, was strong evidence to justify the vaccination officers in employing solicitors to prosecute. Mr. Justice Channell took this view and himself pointed out the technical nature of the defences usually raised in vaccination cases. He therefore held that the vaccination officers had acted perfectly reasonably in employing solicitors to assist them and in employing them from the beginning to the end—that is, to apply for the summons as well as to support it. He did not go so far as to decide that the discretion given to the vaccination officer to employ legal assistance under Article 29 of the Vaccination Order of 1898 enabled him to do so in all cases without question. The correctness of his judgment in doing so must be liable to review in a court of law, should it be questioned. No one interested in local affairs and local finances would wish this to be otherwise. The employment of legal assistance in all cases by vaccination officers would be useless and costly and no one desires that the expenses of the administration of the Vaccination Acts should be increased unnecessarily. Considerable increase of these expenses, however, will have been caused quite unnecessarily to their ratepayers by the guardians of Wandsworth and Clapham, for not only the costs of the actions to which we have referred will have to be paid, as has been said above, but the actual amount of the judgments obtained, being the sums paid for legal assistance, must have been considerably augmented owing to the guardians' attitude. Mr. Justice Channell did not conceal his views upon this subject. He said, according to the *Times*, "that as long as boards of guardians were found who set themselves up in opposition to the law under which they had been elected, so long would their constituents be put to wholly unnecessary expenses. It was entirely the conduct of the guardians which had driven these gentlemen to seek legal assistance and if people were so foolish as to elect such people they must pay for it."

ACUTE HEPATITIS WITH JAUNDICE IN SECONDARY SYPHILIS.

JAUNDICE is a recognised complication of secondary syphilis but as a symptom of severe disease of the liver (*ictère grave*) it is very rare. Fournier in the course of his vast experience has observed only 25 cases. At the meeting of the Société Médicale des Hôpitaux de Paris on March 4th M. Armand Siredey and M. Henri Lemaire described the following case. A girl, aged 18 years, was admitted to hospital on Jan. 9th, 1904, in a delirious condition. She could not furnish any history of her illness. On the next day one of her friends gave the following details. In August, 1903, she left home and began to lead a dissolute life. On Nov. 1st she returned ill and wasted and complaining of lassitude and severe pains in the head which became worse in the evening. Some days later she showed an icteric tint which gradually increased until the end of 1903. Then there was a slight remission of short duration which was followed by an increase of the jaundice. The latter persisted up to the time of admission. At the beginning of December there were violent pains in the lower abdomen and profuse leucorrhœa. Abundant epistaxis took place on Dec. 25th and 26th. On Jan. 8th, 1904, she suddenly became greatly agitated and in the evening she was delirious and vomited several times. On the following day she was admitted. She took no notice of questions but cried out or used abusive words. There were masticatory movements of the jaw, slight rigidity of the lower limbs, exaggerated knee-jerks, general hyperæsthesia, and dilatation of the pupils. The skin was of a marked yellowish green colour. The urine contained a little albumin and abundance of bile pigments but the stools were not decolourised. On the abdomen and thorax were numerous "papulo-squamous and papulo-erosive syphilides." On the vulva and at the anus were many mucous patches and on the neck were the "marblings" of a pigmentary syphilide. There were also manifest lesions of scabies, pediculi pubis, and gonorrhœal urethritis and vulvo-vaginitis. The liver was not enlarged. The temperature was subnormal, 97·5° F. On the following day there was profound coma with muscular relaxation. Examination of the blood showed 19 per cent. of mononuclears and 80 per cent. of polynuclears; no microbes were found. Lumbar puncture yielded a yellowish liquid containing numerous lymphocytes. The lumbar region was wet-cupped and injections of biniodide of mercury were given. Death occurred 30 hours after admission. At the necropsy the viscera were found bile-stained. The kidneys were congested. There were double salpingo-ovaritis and peritoneal adhesions in Douglas's pouch. The free ends of the Fallopian tubes were red, thickened, surrounded with false membrane, and adherent to the ovaries which were also congested and surrounded with membrane. The brain and spinal cord were congested but showed no lesions. The liver was of normal size; on section the right lobe showed a mahogany-brown colour with little yellowish masses which projected from the surface; the left lobe, on the contrary, showed a dark brown surface traversed by fibrous bands of a greenish tint and was more resistant than the right lobe. Microscopic examination of the left lobe showed extensive destruction of the cells which were in process of atrophy accompanied by fatty degeneration. They were surrounded by meshes of connective tissue, sometimes thin and sometimes dense and thick. The right lobe showed similar changes but less in degree. The kidneys were in a state of acute nephritis. A similar condition of the liver has been found in other cases of syphilis, acquired and hereditary. We may add that in the Transactions of the Pathological Society of London for 1867 the late Dr. Hilton Fagge recorded a case very similar to that reported above. A young woman had jaundice and died comatose in the sixth month of a secondary syphilitic eruption. The liver was found to be of an opaque bright yellow colour and dense consistence; it was infiltrated with nucleated fibroid material resembling that described by Gubler and others in infantile syphilis.

TWO GREEK PHYSICIANS AT THE COURT OF THE CÆSARS.

IN a passage referring to two medical men who were brothers and whose patients included members of the reigning family Pliny has left a record of the magnificent emoluments of medical practice in Rome under the Emperor Claudius.[1] He gives the name of one brother as Q Stertinius and we know that the other was C. Stertinius Xenophon who is twice mentioned by Tacitus.[2] These brothers came originally from the island of Cos and were members of an Asclepiad, or medical family, there; their grandfather, whose name was Xenophon, lived in Cos. A variety of particulars relative to C. Stertinius Xenophon and his family have recently been learned from inscriptions discovered at Calymnos and at Cos. The first which was brought to light makes only an indirect reference to the Xenophon of the Emperor Claudius but does so in a significant manner. It is a text in honour of a certain Cleonymos and in it one of his principal claims to notoriety is his relationship to C. Stertinius Xenophon. This latter personage, the text tells us, was a Roman citizen and had once been a tribune in a Roman legion. This almost certainly was the personage referred to by Tacitus and another inscription found about the same time near by, speaking of him as a friend of Augustus and of Claudius, confirmed this view. Subsequently three other texts were found all honouring Stertinius Xenophon, and the series explains to us that the brothers Cleonymos and Xenophon were sons of Heraclitos who we know, from one of the documents, was a son of a Xenophon. The text which tells us this genealogical fact is one relating to C. Stertinius Xenophon's uncle, Tiberius Claudius Philinos, whose friends, when inscribing a statue base in his honour, thought it advantageous to him to mention that C. S. Xenophon, the great man at Rome, was his nephew. But more than this it tells us that this nephew was in the medical profession. For the purpose of illustrating the career of the younger Xenophon of Pliny and Tacitus all these inscriptions are insignificant compared with a long one which was the last epigraphical evidence relating to him to be discovered. We have of this record some 18 fairly complete lines. These relate that C. Stertinius Xenophon was chief physician to the Imperial family and subsequently, at his native Cos, priest of the Asclepiad deities, Hygeia and Epione. For us, too, it divulges a most interesting episode in his career, for it relates that he had been a *præfectus fabrum*, or officer of pioneers, in the Roman army under Claudius in the British war and conducted himself with such distinction as to receive special honorary insignia from his general. It is not known whether he died and was buried in Italy or in his native Cos, but at any rate his admiring fellow islanders have not suffered his memory to be forgotten.

THE PARKES MEMORIAL PRIZE.

THE above-mentioned prize, which consists of 75 guineas and a bronze medal, is awarded every third year to the writer of the best essay on a subject connected with hygiene. The competition is open to the medical officers of the navy, the army, and the Indian services of executive rank on full pay with the exception of the professors or assistant professors of the Royal Army Medical College during their term of office. The subject for the next prize is as follows: "On the Sanitary Requirements of Naval and Military Units in Peace and War, with Suggestions for a Complete Scheme of Sanitary Organisation suitable for both the Navy and the Army." The essay is to be illustrated as far as is practicable from the personal experience of the writer and all essays must be sent in to the secretary of the Parkes Memorial Fund, Royal Army Medical College, Examination Hall, Victoria Embankment, London, on or before Dec. 31st, 1906. Each essay must bear a motto and must be accompanied by a sealed envelope bearing the same motto and containing the name of the competitor.

A HEAVY FINE INFLICTED UPON A QUACK.

A MAN named Lewis Hirst, summoned recently at the Bradford police court at the instance of the Medical Defence Union for taking and using a title implying that he was a qualified medical practitioner, was fined £40 and £1 8*s.* costs with the alternative of two months' hard labour. The evidence as to the infringement of the Medical Act showed that to two witnesses who called at the house where the defendant carried on his trade and who said when he appeared that they "wanted to see a doctor," he replied "I am Dr. Hirst." A bill containing his advertisement also stated that a "qualifying surgeon" was in attendance. If this expression is correctly given in the account of the proceedings before us it must be taken as implying qualification to the ignorant who would understand it to mean a "qualified surgeon," and as intended to leave a loophole of escape to the quack who would deny that he represented himself to be qualified. It may be, however, that the word "qualified" was in fact used and the matter is not of great importance as no doubt, in inflicting the exemplary sentence which he imposed, the stipendiary magistrate was largely influenced by proof of the extent to which the quack was prepared to impose upon the humbler members of the community under the disguise of a medical title. A witness who had shown to Hirst his arm was asked, apparently by the solicitor for the defence, what he was suffering from and he answered "nowt"—a reply the truthfulness of which was not questioned. The defendant, however, had said that the pretended patient's "blood was out of order" and had added that he would make it right but that it would take him about three years to do so. It is not surprising that the stipendiary magistrate observed that such a case was an extremely bad one and pointed out how much the public were indebted to the Medical Defence Union for instituting the prosecution. We observe that the business carried on was advertised under the name of "King and Co.," but apparently no point was raised as to the existence of any company and as to the position of the defendant with reference to it.

[2] Annales, lib. xii, cap. 61 et 67.

THE DISTRIBUTION OF PLAGUE.

THE medical officer of health of the Cape Colony reports that the state of plague in the colony during the week ending April 2nd was as follows.—No case of plague was discovered throughout the colony during the week, but at Port Elizabeth 96 rats and 40 mice were bacteriologically examined, of which 10 rats and 2 mice proved to be infected with plague. In the Cape Town and Harbour Board area 265 rats were examined during the week but none was found to be affected with plague. As regards the Mauritius the Acting Governor in a telegram received at the Colonial Office on April 22nd states that for the week ending April 21st the number of cases reported was 0. As regards the Transvaal the latest figures are as follows:—Suspected cases of plague reported up to April 23rd, 160: coloured persons, 142; and whites, 18. Of these 80 have terminated fatally: coloured persons, 72; and whites, 8.

MUCO-MEMBRANOUS COLITIS AND ITS TREATMENT.

THE paper by Dr. de Langenhagen which will be found at p. 1186 of our present issue came by a happy coincidence very shortly after we had received from Dr. Bottentuit the paper on Some Forms of Pseudo-appendicitis (Entero-typhlo-colitis, Intestinal Lithiasis) which appeared in THE LANCET of April 23rd, p. 1113. The two papers have been printed in consecutive numbers for the purposes of comparison and mutual confirmation but in thus presenting the views of these physicians we do not wish our readers to assume that we entirely endorse them, still less that we hold a brief recommending the treatment carried on at Plombières as superior to that at Vichy, Carlsbad, or many other English or continental hydropathic centres The two articles are left to speak for themselves and they supplement each other in an interesting manner. Dr. Bottentuit's contention is almost a protest against the prevailing fashion of appendicitis; at all events, he calls attention to two conditions often associated and often mistaken for appendicitis. The name of the first is sufficiently ponderous—viz, "muco-membranous entero-typhlo-colitis," formerly known as "catarrhal enteritis." The second is happily more simple—viz, intestinal lithiasis—and, like the former, it is stated to be dependent upon a gouty or arthritic diathesis. In this paper the author is content to indicate what he believes to be the diagnostic features which will conduce to the avoidance of error and he attaches special importance to the examination of the stools for slimy substance, false membrane, or sand. Dr. de Langenhagen, on the other hand, passes quickly over the description of muco membranous colitis to reach the question of treatment. The clinical picture, however, bears strong resemblance to the first condition described by Dr. Bottentuit, though perhaps greater stress is laid upon the importance of atony of the large intestine His description of the treatment he advocates is very full. The dietary, with the exclusion of fat and green vegetables and the substitution of very small quantities of rusks in place of bread, would appear to offer grave difficulties. His main contention, however, is a plea for thorough systematic irrigation of the intestine with a quart or a quart and three-quarters of water at a temperature of from 35° to 45° C. slowly passed in at a low pressure. From what is said of previously boiling the water used for irrigation and of the admixture of various softening or medicated substances it is obvious that this treatment might be conducted anywhere under skilled guidance and with proper appliances. A third feature, the "hydro mineral cure," is, according to this author, only to be carried out satisfactorily at Châtelguyon or at Plombières. The former is advocated for drinking the water when constipation is a marked feature, while special advantages are claimed for the baths and irrigation at the latter when catarrh is intense and neurasthenic phenomena are pronounced. *The different principles of treatment thus enunciated* might almost be expressed in anatomical phraseology as "from above downwards" and "from below upwards." Seriously, however, whatever opinion may be formed of the treatment in these or other hydropathic resorts there can be no doubt that good service has been done in these two papers if they direct attention to conditions which are frequently ignored. It is to be feared that operations for supposed appendicitis may sometimes be undertaken when perhaps a little further patient investigation might have led to less heroic but more satisfactory measures.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

As has already been announced in our columns the first general meeting of the Metropolitan Street Ambulance Association will be held on May 2nd, at 20, Hanover-square, London, W., when Mr. Reginald Harrison will take the chair. The following three motions will be proposed:—

1. Proposed by Sir William S. Church, President of the Royal College of Physicians of London, and seconded by Sir E. Cooper Perry:—

> That this Association, having considered the present condition of [illegible] ent and [illegible] st there [illegible] l ambu- [illegible] o rapid transport.

2. Proposed by Mr. J. Tweedy, President of the Royal College of Surgeons of England, and seconded by Sir Alfred Cooper:—

> [illegible] m [illegible] Lo [illegible] provided and maintained.

3. Proposed by Sir Thomas Barlow and seconded by Mr. G. H. Makins.—

> That the foregoing resolutions be communicated to the London County Council by deputation and that the officers of this Association be requested to arrange for the coöperation and support of other representative associations and persons for this purpose

It is to be hoped that a good attendance of medical men will assemble so that the public and the London County Council may see that the movement is an important one in behalf of a much needed reform. The present position is discreditable to the largest city in the world and a source of danger to the public We have every reason to believe that the London County Council is alive to the seriousness of the situation and wishful to adopt, at any rate in substance, the views of this association.

THE INFANTS' HEALTH SOCIETY.

WE have received a letter signed by the Duke of Portland, the Earl of Mansfield, and other influential gentlemen intimating that the Infants' Health Society was founded on Feb. 11th and that one of its objects is "to spread a knowledge of, and to put on an organised basis, the best methods of systematically dealing with the chief factors affecting the health and life of infants." The society has appointed a special committee to carry on the Infants' Hospital which was established in March, 1903, and is situated is Denning-road, Hampstead, London, N.W. The hospital, therefore, serves as a nucleus for the propagation of the society's views and as an illustration of its methods. The Duchess of Teck is president of the society and the Earl of Mansfield is chairman. There is a large general committee, in which ladies are in a slight majority; the medical members of the committee are Sir Alfred D. Fripp, Dr. Henry Ashby, Mr. A. W. Mayo Robson, Dr. F. M. Sandwith, and Dr. Ralph H. Vincent. The bankers of the society are the London and County Bank (Westminster branch) and the secretary is Mr. R. R. Garratt, 120, Victoria-street, S.W. Membership of the society is open to all who sympathise with its objects. The hospital is entirely free to the infants of the necessitous poor, no payment of any kind or letters of introduction being required.

ST. BARTHOLOMEW'S HOSPITAL.[1]

THIS is a little 32-page pamphlet adorned as to its cover by a sketch of the Good Samaritan by the President of the Royal Academy. *Pace* Professor Clifford Allbutt, we do not like the term "Bart.'s," but, after all, it is no worse than "Powle's," as our ancestors used to call St. Paul's Cathedral. Be this as it may, Sir W. P. Treloar's appeal is well written. It is short, convincing, and set forth by a plain business man for his fellows of like kind. We need not here recapitulate the arguments which we put forward in the columns of THE LANCET of Dec. 5th, 1903, p. 1587, as to why St. Bartholomew's Hospital should continue to stand where it has stood for 800 years and why the citizens of London and all those interested in the hospital should subscribe. The City of London is never behindhand in works of charity and St. Bartholomew's Hospital is pre-eminently the City hospital. We hope that all those whom Sir W. P. Treloar's appeal reaches will read it and will accede to the request therein set forth. In round numbers £500,000 are wanted. Let it not be said that the citizens of London and those whom the hospital has sent to all parts of the world have been asked in vain.

THE DIAGNOSIS OF FRACTURE OF THE BASE OF THE SKULL.

IN a fracture of the base of the skull most of the signs of fracture met with in the bones of the limbs are wanting. There is no deformity, no abnormal mobility, no crepitus, and we have to depend on collateral evidence of the fracture. Hæmorrhage from the ear is greatly valued, and deservedly so, for it is usually produced by a fracture passing through the middle fossa and involving the tympanic cavity, while it is also necessary that the membrana tympani should have been torn. Hæmorrhage from the ear after a fall may, however, be due to a local injury to the external auditory meatus. We print on p. 1235 of this issue of THE LANCET a communication from a correspondent who reports a case of severe injury to the head followed by hæmorrhage from the ear and from the nose. Temporary deafness also was present on the same side, and our correspondent suggests that fracture of the base of the skull had occurred. This diagnosis is very likely to be correct and the fact that the patient was never laid up and that no ulterior results ever occurred in no way tend to discredit the diagnosis. It is not improbable that fracture of the base of the cranium is more common than is thought and that it is present in many cases in which it is not even suspected. Unless it is rendered manifest by hæmorrhage or by the loss of cerebro-spinal fluid it is impossible to be sure that a fracture of the base has occurred. From the point of view of therapeutics it is well to treat all doubtful cases with the same care that would be given to obvious fractures of the base.

CHILDREN'S COUNTRY HOLIDAYS FUND.

THE annual report of the work done by this excellent fund was presented at a meeting held in the Hôtel Métropole on April 28th at which, in the unavoidable absence of the Duchess of Albany, Princess Alexander of Teck presided. The number of children sent away by this fund during 1903 for a little bit of country or seaside life amounted to 34,434—nearly 200 more than in any previous year. This number cannot be largely increased, however, until the various schools close at different times for the holidays. Most of the children sent away were distributed among more than 1000 villages, where they resided in cottages. A new and pleasing feature has been introduced by the supply of boxes of games and books on country subjects for the amusement of the children at some of the villages. Gifts of games and books have been very welcome in this connexion. The subscription list, although greater than that of 1902, is less than that of 1901 by £1800. The Earl of Arran has undertaken the duties of treasurer in place of the Hon. A. Lyttelton who has not been able to spare the time necessary for the work since he became Secretary of State for the Colonies. It is to be hoped that the Children's Country Holidays Fund will be enabled to continue its good work this year in a still more satisfactory manner.

IN connexion with the recent visit of the King to Copenhagen Professor Thorvald Saxo Viggo Petersen, physician in ordinary, and Professor Jens Schou, surgeon in ordinary, to the King of Denmark, have been made honorary Commanders of the Royal Victorian Order, and Dr. Christen Martin Wittüsen le Maire, resident surgeon to the King of Denmark, has been appointed honorary member of the Fourth Class of the same Order.

Mr. Edwin Fullarton Hatton, M.D. Toronto, M.R.C.S. Eng., superintendent of the lunatic and pauper asylums and medical officer of the No. 2 district of the island of Grenada, has been appointed by the King as an official Member of the Legislative Council of that island.

THE annual dinner of the Epidemiological Society of London will be held at the Grand Hotel, Trafalgar-square, London, on Thursday, May 12th, at 7.15 P.M. The chair will be taken by Dr. B. A. Whitelegge, C.B., the President of the society.

THE festival dinner of the City of London Hospital for Diseases of the Chest, Victoria Park, E., will be held at the Hotel Cecil on Friday, May 13th, at 7 for 7.30. The Right Hon. the Lord Mayor of London will preside.

THE annual Medical Mission meeting of the Church Missionary Society will be held in the Queen's Hall, Langham-place, London, W., on Wednesday, May 4th, at 7 P.M.

EDINBURGH UNIVERSITY CLUB OF LONDON.—The May dinner of the Edinburgh University Club of London will take place at the Criterion Restaurant on May 11th at 7.30 o'clock. Sir Robert Finlay, K.C., M.P., Lord Rector of the University, will preside and amongst those who have accepted the invitations of the club are Mr. Justice Darling, Mr. J. M. Barrie, Captain Robert Marshall, and others. It is expected that a large number of members will be present to support the chairman.

[1] "Bart.'s": its Past, Present, and Future. An appeal to the Citizens of London. By Sir William P. Treloar, Alderman, chairman of the Special Committee appointed to collect funds for the reconstruction of St. Bartholomew's Hospital.

SOME REMARKS ON PATHOLOGICAL SCHOOLS.

BY EDWARD S. PRIOR, M.A.,

ARCHITECT OF THE CAMBRIDGE UNIVERSITY NEW MEDICAL SCHOOLS.

A NEED has come for a fresh departure in the planning and construction of schools for special purposes. The architecture of such schools has long been at the mercy of the traditional idea that building is a compromise between the ornamental styles—that are considered those of art—and the building ways—that are considered those of modern construction. The fact is that the systematic training of architects has been almost entirely in the technicalities of house and church building. Architecture has been defined in the terms of such building, and the planning of schools has been evolved mostly as a hybrid—some cross or other between a mansion and a religious meeting-house. No doubt one class of school, that of the school board, has emancipated itself in some hands and has been built for its purpose. But even with this model how few are the private or public institutions for scientific education that show building individuality or such adaptation as declares specifically the object for which the building exists. Whether that be divinity, music, or shorthand, planning and construction usually have kept to a colourless unconsciousness. But even the school board model is not adapted for the more technical kinds of school building. The accommodations of these are not for classes taught orally but for students trained in laboratories (rightly called working rooms), by working in which scientific practice grows into the habit of the student's life. The medical school is, perhaps, the most special of such laboratory schools and has many needs which cannot be approached on the basis of ordinary architectural method. Its essentials of efficiency differ widely from those of a church, a mansion, or a public building. The canons, say, of the architectural competition as to planning would be hopelessly at fault in judging of the plan of a pathological school. And no less does the construction of such a school stand outside current building practice. Not only must it have special provisions for its economy but even a wholesale rejection of many time-honoured traditions of building. To some extent this is true of all medical building in which scientific sanitation is attempted, and it may be thought that the medical s[illegible] comes under the heading of hospital architecture. E[illegible] practice the hospital model takes one but a little way. The ward system, with its lighting and ventilation, its isolations and publicities, the effective combination of which makes the hospital plan, has no counterpart in the necessities of a building which is essentially not a dormitory but a workshop; which is no caravansary for sojourners under observation but rather a group of cells for the training of neophytes, the hermits of science who may attain perfection.

I propose here to give some slight account of the steps which lead the planning and construction of the pathological school away from the traditions of ordinary building, and I deal first with *construction* because in it we have the foundation of planning which is conditioned by it to an extent that is sometimes not perceived. The fact is that houses and churches have so long [illegible] compromise as to the [illegible] and take between wha[illegible] to be built—has left little remembrance of itself. But all forms of building art are based on such a compromise: and when new needs of convenience arise then a new review must be made of the facts of construction, and the terms of agreement between art an[illegible] seen at once how the [illegible] divergence from the [illegible] of building for some centuries has developed itself in a system of *face work*—the deliberate masking and draping of the lay figures of bare construction. The misfits have been taken quite unconcernedly—disregarded hollows have been allowed to multiply beneath the skin of style. But such get full of fluffy dust or worse; they are the lairs of black-beetles, spiders, rats, and mice, so that an old house is indeed a place of many mansions—a zoological museum with whole sets of uncatalogued specimens. Now a pathological or bacteriological school ought to be aware of what it propagates, lest by chance the cultures, the observation of which is its business, prove too successful and escape where they cannot be controlled. The medical building really cannot follow the older traditions; the signal is at danger and the art of building must be switched on to a new course in order to run with ordinary safety.

The essentials of construction for medical schools are: (1) perfect solidity of all the inclosing construction, so that no unfilled spaces are left in its walls, floors, or roofs; (2) a smoothness of all the surfaces and the elimination of all *crevices and ledges for dust*; and (3) such a treatment for all corners and angles that they can be easily and thoroughly cleaned. How far this means a revolution of ordinary building modes will be understood by anyone who will look at an ordinary building in course of construction.[1] For example, joisted floors are mostly but a series of catch-pits into which dust and dirt perpetually drift and which are quite uncleanable. Most of the patent concrete floors have hollowed spaces in their body and are open to the same objections. Then the whole tradition of wall ornament, of its skirtings, surbases, cornices, of its door architraves and window linings, fosters not only the numberless little zoological lairs which we have hinted at, but a system of elaborated dust ledges, such as spring cleanings never thoroughly clear. Moreover, the habit of cubic construction makes corners into which no cleaning implement can find its way; nests where without disturbance dirt colonies may live for generations.

Now it is possible to build without accepting the laws of all this tradition and (though it is not to my point here) the art and beauty of building need not suffer by their rejection. For though these cornices, architraves, &c., are now the associations of architectural taste, yet it was strictly in the meeting of definite needs that these associations were created, and other needs can produce new associations of equivalent value. If we build for the direct object of cleanliness we shall create associations of taste. For the beauty of art seems to spring insensibly out of the simple expression of some direct need. It has certainly always been so in the building art. The simple necessity of vaulting in stone was an impetus to Gothic art, and vaultings of perfectly unadorned construction are beautiful. A clean unequivocable building for the purpose of defence was the Château Gaillard and of it said Richard Cœur-de Lion, "Is she not fair, my one-yea old?" Certainly so far as the constructed shell of a building is concerned, there need be no concealed vacancies, no square angles, no projecting dust traps; doors and windows can be smoothly modelled and need have no architraves or other trappings of traditional architecture; skirtings and cornices [illegible] of additions [illegible] and shaped [illegible]e art of all such building need be none the worse—nay, rather the better—for its independent return to first principles and the rejection of the creeds of some outworn art. Finally, roofs (though this is the hardest task) can be such constructions of concrete and steel that the necessary spans are covered on the safe principles of smoothness and solidity, with no residuum of unventilated crannies, with no unsuspected catchpits and vantage-points for dust, not even a rivet-head need project. There are adaptations of present day materials which can build all this without difficulty or expense; the desire to do it has only to be urgent and the way is open. Again, the finishing of the rooms of a medical [illegible] same lines of construction [illegible] can claim help from one or [illegible]at of "bracket-bricks" or [illegible] of all supports, we can use [illegible] certain patent slabs which [illegible]inciple, if steadily adhered to, will allow perfect cleanliness if it does not actually enforce it. It is this—that the level tops and all ledges or holes that are necessary should be where they are directly open to the eye; and secondly, where their cleaning can be thorough and systematic. All the furniture of a laboratory can be constructed and placed so that it is sealed from dust as to its interiors and so that its exteriors can be submitted to constant cleansing.

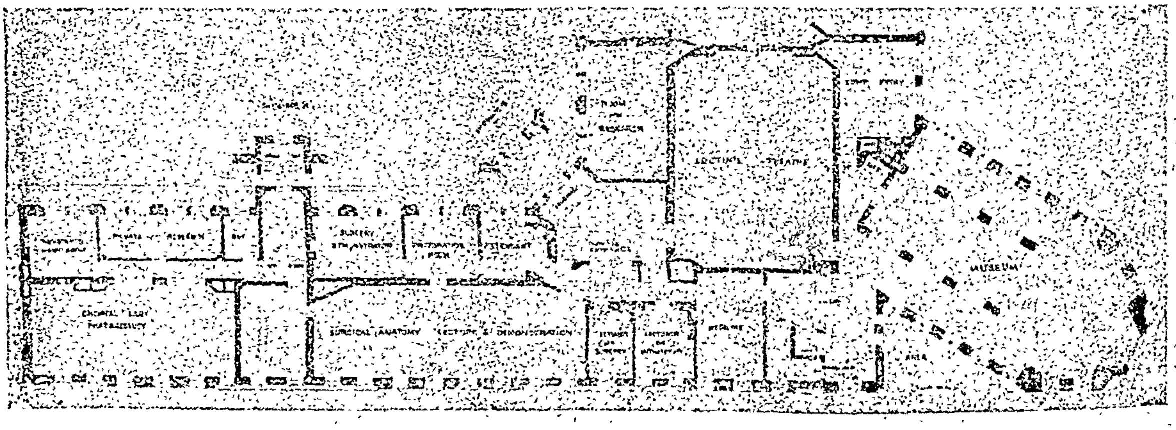
There are difficulties, no doubt, with the pipes—the light and water conductors—the wastes, taps, sinks, and shaftings of a laboratory. The wastes can be glazed channels in the floors, made to run straight to the outside of the building, with removeable covers so that their whole lengths can be constantly inspected and flushed. All pipes can be best managed by their being placed on the walls where they can be directly got at and where the least accumulation of dust and dirt about them can be detected. They should be painted white so that the dirt may be conspicuous and this provocation to cleanliness should be everywhere adopted, for it is fortunately supported technically by the fact that white paint is the only pure paint, all colouring added thereto being a detrimental adulteration. The stair flights of public buildings as ordinarily constructed provide many little fastnesses for the dirt tribes from which no cleaning implement can drive them, but construction can minimise the deeply set angles where the treads abut on the walls and there is no necessity to add to medical staircases such accessories of style as dust-catching balustrades. The science of sanitary materials for wall surfaces has for some time received considerable attention in hospital construction and I do not propose to enter on the discussion of specialities as to which rivalry exists. But one may point out as extraordinary that while there has been keen competition among the manufacturers of perfectly smooth non-absorbent substances in the way of glazed tiles, &c., the pertinent facts as to the fixing of these tiles and ultimate history of their glazes have been disregarded. Most of the glassy wall coverings offered have the objection that, perfect in themselves, their joints cannot be made thorough, so that the attachment of them to the walls leaves crevices. And too often the most glassy surfaces carry in themselves the seeds of destruction. In fact, the higher the glaze the greater the tendency to scale, owing to the high tension and the uneven contractions of the surface and under material. The best success has been with the thick rougher glazes and coarser makes the jointings of which can be made thorough.

---

[1] The extent to which what appears solid in building is really cellular is not generally understood. Many walls are built purposely hollow and, with purpose or not, the trade bricklayer using as little mortar as possible leaves the walls half air-space.

The sketch I have made above of what is possible in laboratory construction has to be supplemented in many particulars. Especially the controversial question of heating and ventilation has to be reckoned with, since decision on this point involves many constructional consequences. Particularly the mechanical appliances necessary for the shifting of the air and the fittings required to regulate its proper course throughout the rooms must be so applied that they do not create those dirt traps and that dust concealment which all the rest of construction has striven to minimise. The lighting of laboratories is also a special point in their architecture and one that is often shirked or considered as an afterthought instead of a consistent factor in the problem of their design. For most of their purposes north light is the only one that is satisfactory. East light is better than west, since the use will be more often in the afternoon, but south lighting should be used only for the less distinctive departments and offices of a medical school. But it is the make of the windows that needs specialising, seeing that their use is to light microscope practice. They have to be made convenient for two ranges of tables, one at the windows and the other back in the room. It has been found that at table-height and at a distance of ten feet (which is a convenient distance for the second range of microscopes) an unbroken oblong opening of glass 24 by 20 inches gives the proper field. The divisions to carry such sheets of glass need to be strong and so are best of iron. There is no need to make them thick stone mullions and transoms, as under the belated traditions of style is often done as a sort of compromise between use and art. For art's sake the top lights are glazed in little squares; while for use formless big sheets below advertise themselves as in obvious disagreement. Indeed, thick mullions and the heavy transom become particularly bad for the microscope that has to be used at a distance. The best lighting of a working laboratory for a class of students where tables have been ranged behind one another is that of the weaving shed, with north sloping skylights. But in order that the necessary bars of the skylight construction may not spoil the microscope field for work at the tables the height of the room must be as low as possible. The nearer the skylights are to the work the greater the unbroken spaces in the reflection. Such weaving-shed roofs require careful construction to be successful. The ordinary steel building of roofs has had no thought of minimising to the utmost the ledges for dust and dirt.

It will be seen how immediately these essentials of lighting connect the constructive question with that of planning and arrangement. Where the aspect and construction of certain rooms are exactly indicated by the conditions of microscope use the available spaces must be mapped out accordingly. The plan must provide for the constructions necessary to this purpose and dispose the other parts of the building to suit. Besides the laboratories in which microscopes are in use the equipment of a medical school needs lecture theatres and oral class rooms. Now here, too, we come upon conditions which separate the building of the medical school from that of others. Under modern conditions of teaching by the projection lantern the use of artificial light in the medical lecture room is almost constantly required. Hence it is want of economy laboriously to give what is not wanted for the lecture theatre, an outlook upon open areas the wealth of daylight of which is of such importance elsewhere. Yet so strictly does architectural convention apply its canons that the building of a room without admission of daylight to it is reckoned a freak. For the pathological school this vagary is, however, not only to be sanctioned but made the direct way to success in planning economically and to the purpose of the building.



The ground floor of the Cambridge Medical Schools, showing the lecture theatre dependent entirely upon artificial light.

On all sides do the conventions which govern the planning of most public buildings fail us for the dispositions of a medical school. Access by means of broad corridors, the symmetrical approach to the rooms and the serried arrangement of them in sets are the qualities which show well in the paper planning of our public buildings and obtain their reward by success in competitions. But the medical school needs none of these and indeed must count all such stateliness as waste of space. The arrangements of workshops and factories, not those of public offices, are most convenient to it. It must cluster functional departments round the laboratories, giving immediate openings from room to room and providing a general inter-communication in which much corridor is inconvenient. In its lecture theatre and libraries and museums no doubt the ordinary arrangements for allowing easy approaches must be studied, but with many differences from those in use for a less special institution.

As to its lecture theatre, a large preparation room should be immediately attached to the rostrum of the lecturer whose table should be in sight from all the benches and provided with special arrangements for lantern work. It is a useful point that the access corridors by which the students reach the theatre should be large enough to have cases set in them, so that the students passing in or out may supplement the lecture by personal study of specimens illustrating the subject treated.

The library, just as the lecture theatre, should of course be centrally placed and easy of access. Seeing that the majority of books to be consulted by the medical student are special rather than general works, there need not be those facilities for reference to open shelves which general libraries develop to the full. The block system of stacking the books together, with bookcases that pull out into the room, should be used for
spaces for a student's ta
library of a medical scho
be easily consulted. In the same way the medical museum is not quite on the lines of other museums, since its specimens have constantly to be brought into the lecture theatres and laboratories.

Another special department of the medical school is that which provides the rooms for private research. As already said, the scientific education does not lie in a few years' attendance at lectures but is the inducement to a mental habit to be exercised on constant experiment. The placing of the student where he can proceed with definite work is the necessary complement of his preliminary training. Now to equip all this experiment there are many special depart-
must provide—rooms for
illation, for freezing, for
aphy, glass-blowing, &c.
All this bears out my initial definition, that the basis of the medical school planning lies in the idea of workshops or scientific factories. And in this connexion one necessary provision, that of sheds and stables where can be properly housed both the larger and smaller animals necessary for pathological experiment, can be seen to mean a very special contrivance in the planning.

[To give some distinctness to the variety of feature which the arrangement and equipment of a medical school involve Mr. Prior inclosed the plans of the Government laboratories at Netley which the War Office proposed to build for the Army Medical Service. The arrangements were planned under the direction of Professor A. E. Wright and Professor

Since there was a perfectly open site for this building the dispositions were unfettered and an order and symmetry could be adopted which the very confined site of the Cambridge Medical School did not allow. The latter, however, when completed, will deal with a much wider range of
ose of
refer
s new
and highly successful medical schools at Cambridge, which were opened by His Majesty the King at the beginning of last month (see THE LANCET, Feb. 27th, pp. 599 *et seq.*). It will be seen by that article how closely Mr. Prior has adhered in practice to his tenets, and it will be admitted that his buildings have lost nothing æsthetically by his intention to subordinate every feature, whether of construction or ornament, to his aims of practical utility.—ED. L.]

THE ROYAL ACADEMY.

THE one hundred and thirty-sixth exhibition of the Royal Academy of Arts, which will be open to the public on Monday next, contains many good and interesting pictures. There are others deserving neither qualification and it would be surprising if this were not the case, for the rooms at Burlington House contain nearly 2000 pictures, water-colours, drawings, miniatures, sculptures, and bronzes. On the whole, the level of achievement, we think, may be considered high, certainly higher than that attained by the other annual exhibitions. The hanging committee has had regard to modern developments in painting and the old Academicians have only sparingly availed themselves of their vested right to space, so that room has been found for a representative collection of works of art of which, as a non artistic people, we need not be ashamed.

Of course, there are some dreadful presentation canvases, dull scenes or unlovely people in unbecoming costumes, whose features no painter's skill has been able to make into a pleasing show. But there are, on the other hand, some beautiful portraits, Mr. Sarjent and Mr. Shannon in particular carrying on the traditions of Reynolds and Gainsborough. Mr. Sarjent sends six large portraits, three of women—Lady Lathom, the Duchess of Sutherland, and Mrs. Wertheimer—and three of men—Lord Londonderry, Major General Wood, and Mr. Devitt. Of these the women are the best. Not that they have necessarily had the most care bestowed upon them, for probably the portrait of Lord Londonderry in Coronation costume, bearing the sword of state and attended by his page, is the most elaborate of all. Nor have concessions been made to prettiness in the female portraits, for the Countess of Lathom is represented with a markedly asymmetrical mouth, while her arms and hands do not strike us as being elegant factors in so stately and highbred a total. Still, it is impossible not to feel that the portrait is a lifelike though uncompromising representation of the sitter, and the same may be said of the somewhat smaller portrait of Mrs. Wertheimer. As in the case of Lady Lathom the colour scheme here is sombre, but the blacks and greys and yellowy browns make up a very pleasant picture. The Duchess of Sutherland, on the contrary, is painted in a glorious metallic green robe, contrasting vividly with her sunny hair. She has a high colour and a bright smile and is altogether a very satisfactory example of young and splendid womanhood. Mr. Shannon sends four portraits—Mr. Martin Harvey in his well-known representation of "Sydney Carton," Sir William Emmerson, the President of the Royal Institute of British Architects, Miss Gladys Raphael, and two young ladies, daughters of Mr. W. H. Bell, painted together on a sofa. In this picture Mr. Shannon is particularly happy, the figures are restful, as figures on a sofa should be, the poses are natural, and painter and sitters are alike to be congratulated. Mr. William Orpen's portrait of Mr. Charles Werthemier is a very satisfactory performance. Mr. Arthur Hacker sends an admirable portrait of the Rev. E S. Roberts, for many years tutor and now master of Gonville and Caius College, Cambridge, whose features will be familiar to several generations of Cambridge medical men. Mr. Cope's portrait of Lord Alverstoke, Mr. Herkomer's portrait of Mr. Chamberlain, Mr. Bacon's portrait of Mr. T. P. O'Connor, Mr. Furse's portrait of Sir Francis Mowatt are all sound pieces of work and the same may be said of Mr. John Collier's portrait of Professor Ray Lankester, but in a portrait of Mr. H. T. Butlin this gifted artist hardly does himself justice. Mr. Draper's portrait of the nonagenarian Duchess of Abercorn is worth attention. It is a sympathetic representation of dignified old age, while the pains that he has expended upon the hands should be noted, pains which Mr. Sarjent appears to think waste of time.

Among many good landscapes the canvases of Mr. Joseph Farquharson, Mr. Arnesby Brown, Mr. David Murray, and Mr. La Thangue are noticeable. Two of Mr. Farquharson's four canvases show that he can tear himself away from snow scenes, and it is to be hoped that he will not allow the public, who are so insistent upon an artist repeating himself, to confine him to perpetual midwinter. Several terrible examples this year among the Royal Academicians of the result of the constant treatment of the same theme in the same way should prove a warning. Mr. David Murray continues to paint in Constable's country and it speaks much for his skill when we say that his rendering of Flatford, showing the present appearance of the scene of the master's famous picture, "The Hay Wain," is quite satisfactory. Two of Mr. La Thangue's pictures are Italian scenes and two are English, and all four are excellent, the work of a man who has seen often, and never without learning some lesson, the effects of light, shade, and atmosphere which he depicts.

Sir Lawrence Alma-Tadema sends only one small but characteristic study—some classical ladies looking from a marble building over a blue sea. Sir E. J. Poynter and Mr. Orchardson, who run him close in cultivated favour, send three pictures each, but nothing of the first importance. The President's picture in Gallery II., "The Nymph's Bathing Place," is certainly beautiful, but the lady's skin seems to have been painted more to fit the colour scheme than to imitate anything in life. Her bronze cuticle, with her brown-red robe and her brown-auburn hair, makes a delightful harmony and she is an exquisite young person but to the coldly medical eye she has a funny tint. A picture by Mr. Seymour Lucas in the same gallery, entitled "Finis," shows very skilfully the restful abandonment into which a performer on the 'cello has fallen at the end of his task. The droop of the body and limbs following on muscular relaxation has been accurately caught.

In Galleries III. and IV. will be found most of the portraits to which we have alluded. In Gallery V. the most conspicuous pictures are the central panel of a reredos by Mr. Abbey, whose deliberate mediævalism looks rather out of place in its environment; "Timber Hauling in the New Forest," by Miss Lucy Kemp-Welch, a fine, vigorous, and very large picture; and a symbolical work by Miss Offor. The last is a well painted female figure, but the work is made a little ridiculous by the verse which it is supposed to illustrate, for although the damsel is supposed to be engaged in a long and weary climb barefoot over rocks there is not a trace of muscular exertion in the well-painted body, no scratches mar the contour of her elegant feet and hands, and her legs are entangled in a wrap that would effectually impede the ascent that it is her allegorical duty to achieve.

In Gallery VI there is an impressive little picture by Signor Antonio Mancini entitled "*En Voyage.*" In Gallery VIII. two large allegorical pictures overshadow everything, "Mammon," by Mr. Rob Sauber, and "Despised and Rejected of Men," by Mr. Sigismund Goetze. The latter picture contains some carefully executed types of modern civilisation, the young man of pleasure and the young woman of the same bent, the low sportsman, the bar loafer, the soldier, the man who has come down in the world, the prelate, the deserted mother, and so on. The meaning of the canvas is very obvious and it will probably attract the attention of the public. Two small pictures in this gallery are worth attention, "A Sunny Shore," by Mr. Lionel Smythe, and "The Viaticum," by Mr. Chevallier Tayler. The cleverness of Mr. Tayler's street scene is conspicuous, the crowd of hucksters and loafers forming a piquantly contrasted background for the priest, the holy nature of whose errand is recognised only by the Italian organ-grinder.

In the sculpture gallery we noticed a capital bust of Mr. Alfred Willett, F.R.C.S., and another of the late Sir George Humphry, both by Mr. Hope Pinker.

We close our necessarily brief notice of the oil paintings of the exhibition with a query, Did Joan of Arc suffer from Graves's disease? Mr. Frank Dicksee would have us believe so and Mr. James Sant appears to be of somewhat the same opinion.

LORD CROMER'S ANNUAL REPORT ON EGYPT.

IN a prefatory letter to the Marquis of Lansdowne Lord Cromer expresses a fear that his report "will be found tedious" on account of its length. We do not think that he need be afraid of this. The clear and succinct narrative in which year by year he records the results of his stewardship will always be full of interest for his fellow countrymen. Nothing within the last quarter of a century has added more to the national reputation than the establishment in Egypt under Lord Cromer's guidance of order and solvency instead of anarchy and ruin. It is truly a marvellous piece of work, challenging comparison with events of a similar character whether in ancient or in modern history; but they alone can fully appreciate its excellence who knew the country under the old *régime* and can understand the complicated international tangle in the midst of which all reform had to be effected. In 1883 the fate of Egypt was in the balance. In Lord Cromer's words: "The chaos and confusion, resulting partly from a long course of misgovernment and partly from the special circumstances of the moment, were indeed extreme. ...... Stated in the most general terms the main object to be pursued was manifestly to substitute another bond in the place of that which previously existed and which had recently been strained to the extent of producing what really amounted to a revolution—for it is altogether a mistake to suppose that the Arabi upheaval was merely a military mutiny and nothing more." To save the State from political and social extinction a master mind was needed and happily the occasion brought forth the man. The rehabilitation of Egypt in such exceptional circumstances is in truth an achievement of which every Briton may well feel proud. No wonder Lord Cromer's reports are increasing in length. As he says: "Fresh interests are rapidly springing up. Egypt is in a state of transition and the problem of adapting the whole machine of government to meet the wants of a society which is almost bewildering in the variety of its component parts becomes daily more complex." At first the material improvement of the country could alone be attempted but as soon as possible action was taken towards the moral amelioration of the mass of the population. "I have no hesitation," continues Lord Cromer, "in stating that the action taken during the last 20 years in this field has produced the intended result. At no former period in their long history have the people of Egypt been so prosperous or so contented as at present. The forces of reaction have in well-nigh every direction undergone a signal defeat. The system of personal government as previously practised in this country—which found in those forces its most potent ally—has received a blow from which it can never recover and from which I hope and believe it will never have a chance of recovering." Lord Cromer being well known as the personification of discretion an authoritative statement of this description is most satisfactory.

Turning to the detailed information, which as usual is supplied under separate headings, we find much that has a special interest for medical men and sanitarians. Notwithstanding a surplus of revenue over expenditure at the close of 1903 amounting to upwards of three-quarters of a million sterling no more than about £E.6000 was added to the sanitary budget for the current year. Of this sum £E.2500 were devoted to increasing the number and improving the position of subordinate employés, £E.2000 to the street services of Cairo, and £E.1000 to hospital expenses. The number of admissions into the Government hospitals increases year by year. In 1893 there were 17,473 patients admitted; in 1903 the total number was 25,162. "This is satisfactory," says Lord Cromer, "in so far as it shows that the people are gaining confidence in the hospitals, whereas formerly not a single patient entered of his own free will. It is, however, very necessary to insist on the payment of fees for treatment, save in the case of the really indigent poor. No Government can afford to give medical treatment gratis to the larger portion of the population. ...... The principal function of government is the prevention of epidemic diseases, not the cure of persons suffering from ordinary maladies. The Egyptian Government is still far from being in a position to deal adequately with the former of these two questions." The views here enunciated by Lord Cromer are undeniable. Unless the budget of the sanitary department can be substantially increased it is to be feared that the inability of the Egyptian Government to deal adequately with epidemics of disease will long continue. Still, even as things are, a good deal has been done. "Egypt was entirely free from cholera during the whole of last year," continues Lord Cromer, "2118 cases of small-pox occurred, of which 394 were fatal; 406,856 successful vaccinations were performed, as against 377,421 in 1902. There was a good deal of diphtheria in Cairo during the autumn months. 286 deaths occurred, of which 15 were amongst Europeans. I am informed that whenever the children in the house where one case has occurred have been treated with anti-diphtheritic serum the disease has not spread. Plague appears to be diminishing; 303 cases were notified throughout Egypt, of which 160 were fatal, as against 481 cases and 291 deaths in 1902. The cases in 1903 occurred in the same towns and villages as those which suffered in 1902."

Of sanitary works in connexion with drainage or sewerage Lord Cromer makes no mention. The project for draining Cairo of which so much was heard some years ago seems to have been relegated to the Greek Kalends, and yet with diphtheria prevalent and a death-rate of 42·5 per 1000[1] it is evident that sewers are urgently required. With regard to water-supply, however, Lord Cromer is able to announce considerable progress not only in the capital and at Alexandria but also in several provincial towns. "It is with very special pleasure," he says, "that I am able to record that the Egyptian Government has at last found itself in a position to embark seriously on the very wide field of sanitary reform. There could scarcely be any question as to the point which, more than all others, required attention. Experience has abundantly proved that public health depends in no small degree upon the purity of the drinking water supplied to the population." It cannot of course be denied that pure water is an excellent thing, but if water is laid on to a town there should also be provided some means for its removal when soiled. A water-supply is certain to be followed by water-closets which in the absence of sewers cannot be regarded as unmixed blessings. This is well exemplified in Cairo where the contents of innumerable water-closets are discharged into loose-bottomed cesspits situated among the foundations.

---

[1] Week ending Jan. 14th, 1904.

During the year with which Lord Cromer is dealing the resources of the sanitary department were severely tried by a serious outbreak of cattle plague. Sir Horace Pinching deals with the epizootic in a memorandum of which the full text is given in an appendix and which has been dealt with by our Egypt correspondent in THE LANCET of April 23rd, p. 1161. Referring to this document Lord Cromer says: "It cannot be doubted that the main difficulty in the way of dealing with an outbreak of this sort is to be found in the apathy and want of initiative amongst the people themselves With rare exceptions the Egyptians, from the highest to the lowest, expect the Government to [illegible] s of [illegible] im- [illegible] forts [illegible] form [illegible] s to [illegible] the growth of centuries and the outcome of a long course of misgovernment can be altered in a hurry."

In illustration of "the almost universal tendency to shirk responsibility" which, together with corruption, is a "besetting sin" among Egyptian officials, Lord Cromer tells the following story. "I have heard of a doctor being sent to examine into the condition of a station master supposed to be insane. On entering the room he was attacked and nearly strangled by the madman. He was able, after a sharp struggle, to call on two orderlies who had been present all the time to seize the man. They saluted and did so. On being asked why they had not interfered sooner they replied that they had received no orders to that effect. Without doubt they considered that the struggle on the floor which they had witnessed was part of some strange European process, with which they were unfamiliar, for dealing with insane station-masters."

THE SANITARY STATE OF MADEIRA.

IN view of a recent rumour that typhoid fever was prevalent in Funchal we have made inquiries and are able to publish the following from the pen of a well-informed correspondent:

During the last autumn months of September and October there was a considerable prevalence of typhoid fever in Madeira, mainly amongst the lower classes of the Portuguese people in the crowded eastern side of the city but the cases had already subsided when I returned from London in November. The latest returns covering the month of March give only five fatal cases in the district of Funchal, embracing a population of 145,000 persons. If there are added 20 odd cases returned as diarrhœa in the official list—and these lists are now more accurately kept than formerly—it will be seen that no outbreak has happened which can be termed epidemic in character.

During the last six months there have been 12 cases amongst the thousand or so of visitors and residents of our own people but no deaths have occurred. The hygiene of Madeira is undoubtedly primitive and defective and we are urging the authorities to develop promptly those elementary matters of mountain water-supply and town draining which are first considerations in the equipment of the meanest health resort. I have done my best in this direction and quite recently I went to Lisbon and succeeded in persuading the Lisbon Cortes [illegible] argo annual sum of money to [illegible] in Madeira and I have every [illegible] of water-supply and drainage accomplished before the termination of my long career in this island. The house drinking water is supplied mainly from a deep source in the centre of the district; this is of unquestioned purity and no case or outbreak of typhoid fever has ever been reported from the numberless steamers crowded with passengers which touch and draw their supplies at this port. In the hotels and quintas the drinking water is taken from the same source, but for baths and other domestic purposes mountain water is used which is brought in open channels subject to pollution from the human habitations in its course. In the hotels this is pasteurised in bulk and rendered safe; but it is this supply of two qualities of water which I trust shortly to see superseded by an adequate supply from a mountain district far beyond the contamination of human contact. The plans are all ready and elaborately drawn out and the money, as I have stated, has been voted.

It is impossible to over-estimate the importance of this health station and the absolute necessity of bringing the sanitary conditions up to date. We are now hardly more than three and a half days distant from England and the finest steamers almost daily call here and hundreds of our countrymen land, spend their money, and pass a few hours in exploring the mountain scenery and the surprising garden growths of a sub-tropical region. About 2000 steamers—most of them British—now call annually and land their passengers and take their supplies from Madeira; important industries have developed and the perishable produce of the land is conveyed to distant and less favoured countries with immense advantage to the people and the government of Portugal. In return we expect, as a matter of protection, merely the development of the elementary conditions of modern salubrity.

For two years there has been a serious want of rain in Madeira. We have had far too much fine bright weather and sunshine—agreeable enough to visitors but detrimental to the general interest.

April 7th.

ASYLUM REPORTS.

Ayr District Asylum (*Report for the period April 1st, 1902, to Dec. 31st, 1903*).—The average number of patients resident during the period was 515, comprising 245 males and 270 females. The admissions during the period amounted to 248—viz., 131 males and 117 females. Excluding from these 31 old-standing cases representing an artificial influx of already confirmed and registered pauper lunatics, the direct admissions were 212. Of these 187 were first admissions. Dr. C. C. Easterbrook, the medical superintendent, states in his report that among the admissions 33 were over the age of 60 years and that the mean age on admission was 45 years. A family history of insanity was traceable in 63 cases, of tuberculosis in 26 cases, of alcoholism in 14 cases, and of nervous diseases in 19 cases. Previous attacks of insanity occurred in 81 cases, while a "nervous" constitution or attacks of epilepsy and hysteria had occurred in 50 persons. The varieties of insanity present in the admissions were alcoholic insanity in 58 cases, senile insanity in 32, adolescent insanity in 36, climacteric insanity in 18, insanity of lactation and the puerperium in 12, and the insanities of inherent insane constitution (recurrent insanity, hypochondriacal insanity, and paranoia) in 12. General paralysis was met with in nine cases. Suicidal and homicidal tendencies were exhibited by at least 67 persons, 35 of whom had made suicidal and 32 homicidal attempts. The prospect as to mental recovery was doubtful in 83 cases and bad in 30. From the data collected, says Dr. Easterbrook, "there are two main lesson [illegible] insanity in the count [illegible] and the influence of [illegible] sent as a hereditary factor in 14 instances and as a personal factor in 58 cases. "These 58 cases do not include other 24 persons in whom alcoholism was present as a symptom of the insanity. I have most carefully excluded such cases, wishing to get at the real facts if possible. Further, I have excluded three cases in which I regarded alcoholism as a contributory factor only. ...... This left 55 alcoholic patients in whom the diagnosis of alcoholic insanity was based not merely on the history of the patient's habits but also on the character of the symptoms present, mental and bodily." These 55 cases out of 212 direct admissions represent a proportion of alcoholic insanity of 25·9 per cent., "which, so far as I know, is not exceeded in any other county asylum in Scotland." The evil is thus widespread, but the remedy is less obvious, says Dr. Easterbrook who further suggests perpetual sequestration in "colonies"—islands for choice—for habitual inebriates, criminals, and degenerates who could thus "propagate neither their kind nor their influence and where all should be made to work for their maintenance." The number of cases discharged as recovered during the year amounted to 98, or 19 per cent. of the average number resident. The deaths during the year amounted to 89, or 17 per cent. as calculated on the same basis. Of the deaths three were due to senile decay, ten to pneumonia, 11 to general paralysis, 14 to cardiac disease, 14 to pulmonary and other forms of tuberculosis, and the rest to other causes. The Commissioners in Lunacy state in their report that the condition of the patients was in every respect satisfactory, that the clothing was neat and good, that the asylum was throughout in good order and scrupulously clean, that the day rooms were comfortably furnished, and that the medical case books were correctly and well kept.

Barnwood House Hospital for the Insane, Gloucester (Annual Report for 1903).—The average number of patients resident during the year was 144, comprising 61 males and 83 females. The admissions during the year amounted to 35—viz., 11 males and 24 females. Of these 31 were first admissions. Dr. James G. Soutar, the medical superintendent, states in his report that during the year one man was admitted as a boarder but he left unimproved within a fortnight. Two women were admitted as boarders; one of these had to be placed under certificates and the other recovered but continued in residence longer. Only cases of acute and curable insanity "and those chronic cases who were likely to appreciate or be influenced by their surroundings" were accepted for admission. Among the causes of mental disorder in the admissions hereditary predisposition occupied a prominent place, being ascertained to be present in 40 per cent. of cases. The number of patients discharged as recovered during the year amounted to 19—viz., six males and 13 females, or 13·2 per cent. of the average number resident. The deaths during the year amounted to eight, or 5 6 per cent. as calculated on the same basis. Of the deaths one each was due to general paralysis of the insane, pulmonary tuberculosis, strangulated hernia, and injury on a railway, and two each were due to bronchitis and to cardiac disease. "It is agreed that efficient treatment in the early stage of insanity is that which beyond everything else gives the patient the best chance of recovery and our statistics for the year emphasise this point. Of those who recovered nine had on admission been ill for one week or less, seven had on admission been ill for more than one week but less than one month, and one had been ill for more than a month but less than two months." The health of the inmates was good during the year and there were no cases of epidemic disorder. The Commissioners in Lunacy state in their report that all parts of the building were found to be in good order, that there was no restraint or seclusion, that the patients appeared contented and well cared for, and that the medical case-books were well kept. The committee of management states in its report that "the hospital buildings, both as regards structure and decoration, the character of the establishment, the amusements, comforts, and luxuries provided for the patients, are all planned so as to conduce to the speedy recovery of the curable cases," so that their provision and maintenance have been, and continue to be, very costly. To further this end the committee has during the past five years discharged many patients whose condition seemed incapable of amelioration and it has also refused to admit many others who apparently belonged to the same unfavourable class. The committee has thus gradually reduced the number of chronic and incurable cases in the hospital within a reasonable time.

MEDICINE AND THE LAW.

The Definition of an "Accident."

It is a matter of some importance to a medical man when he is called in to attend a working man to know whether the condition in which he finds him, the causes of that condition, and the treatment prescribed are likely to form the subjects of investigation in a court of law. Consequently recent decisions enlarging and defining the meaning of the word "accident" as used in the Workmen's Compensation Act, 1897, are of interest to members of the medical profession who may have to figure as witnesses as well as to their patients. Moreover, the signification and uses of words of frequent occurrence in the English language must always be worthy of the consideration of educated persons whose native tongue it is and who are in a position to form their own opinions upon the question under discussion. The phrase in the Act concerning which doubt has arisen is that which makes the employer liable to pay compensation to his workman for "personal injury by accident arising out of, and in the course of, the employment." It will be seen that not only must the personal injury be due to an "accident" but also that the accident must arise out of, as well as in the course of, the employment. A large number of occurrences causing injury to workmen fulfil these conditions so plainly that dispute cannot arise. With others, however, it is different. Frequently a workman becomes disabled although no outward fortuitous event such as is often associated with the word "accident" has taken place. Sometimes he has deliberately encountered excessive strain, as for example in lifting a heavy weight, and a hernia or other serious injury or the aggravation of existing injury has been the result. On such occasions medical evidence is necessary in order to explain the injury and to connect it with the workman's employment, but the question whether it has been "accidental" is a matter for judicial interpretation. The Act uses the word "accident" but does not define it. There were conflicting decisions upon the subject until the case of Hensey *v.* White was heard by the Court of Appeal in 1899. This and others which followed the precedent laid down in it may be said to have decided that where the work performed presented nothing fortuitous or unforeseen there was no accident. As an instance of these decisions may be cited the case of Roper *v.* Greenwood (83 Law Times, N.S., 471) in which a woman engaged upon the manufacture of wooden boxes had to turn and to move some heavier than those which she usually handled. Having lifted several with effort but without apparent ill-effect to herself she essayed another but complained at once of injury and was found to be suffering from prolapsus uteri induced by her exertions. This was held by the Court of Appeal not to have been an "accident" such as would entitle the woman to compensation. This case, with Hensey *v.* White and others of the same class, were overruled by the House of Lords in another (Fenton *v.* Thorley, 1903, A. C. 443) which may be described as a typical instance of over-exertion in the ordinary course of work. The workman had to raise the lid of a large vessel by turning a wheel. The wheel worked stiffly, he called a fellow workman and while they were endeavouring to move it felt "a tear in his inside" which proved to be a hernia and for which he claimed compensation. This was refused by the county-court judge whose view was upheld by the Court of Appeal following the decisions referred to. The House of Lords, however, unanimously decided that the Court of Appeal and the previous decisions were wrong and that the workman should be compensated as for an "accident." This word Lord Macnaghten considered to be used in the Act "in the popular and ordinary sense of the word as denoting an unlooked-for mishap or an untoward event which is not expected or designed." Lord Robertson spoke of the word being used to denote "any unintended and unexpected loss or hurt apart from its cause." The result has been that the workman does not now have to adduce proof of an unforeseen incident external to himself and arising out of his work in order to be compensated. He can claim in respect of those results of physical strain of which a willing worker must at times run the risk but the actual occurrence of which neither he nor anyone else can predict. This decision appears to be one in accord with the spirit of the statute and it is one which naturally has brought others in its train. In December, 1903, two cases came before the Court of Appeal in which the workmen had suffered from anthrax contracted in wool factories. Two county-court judges had given contrary decisions, one of them holding that the infection constituted an accident and the other refusing so to regard it. The Court of Appeal declaring the matter to be governed by Fenton *v.* Thorley had no doubt that according to that judgment infection with anthrax was an accident arising out of the workmen's employment. How far the *possibilities* thus suggested *may* be extended in the future remains to be seen. It was said by the county-court judge who refused to treat anthrax as an "accident" that if infection with disease was to be so regarded then a workman who caught scarlet fever from one of his fellows would be able to claim compensation from his employer and it is by no means impossible that some day claims of this kind may be attempted. Yet a third case of doubtful "accident" was more recently heard by the Court of Appeal in which, however, the question turned principally upon whether the occurrence arose "out of" the employment. In this (Andrew *v.* Failsworth Industrial Society, Limited) judgment was given on April 13th. The man whose relatives applied for compensation was employed upon a building which complied with the requirements of the Workmen's Compensation Act in being above 30 feet in height and he was working at a point 23 feet above the ground when he and a fellow workman were struck and killed by a flash of lightning. The expert evidence dwelt upon the danger arising from the height above surrounding objects, upon the effect of wet, and upon the fact that the man would afford a well-defined point at which a discharge might occur. The increase of danger owing to elevation was thus defined: "If you draw a line at an angle of 45 degrees from the highest point of an erection to the earth persons within the cone are protected and it is therefore clear that as you ascend the zone of safety diminishes." The county-court judge held that there was a right to recover for an "accident arising out of the employment" and the Court of Appeal confirmed his decision. It will be seen that the trend of these later judgments is towards widening rather than towards narrowing the scope of the Acts in question and that they are likely to make employers careful of the safety of their workmen in matters with regard to which they could before afford to be indifferent. They will also increase the number of occasions upon which medical evidence will be required.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8789 births and 4697 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had been 18·7, 18·4, and 17·6 per 1000 in the three preceding weeks, further declined last week to 16·0 per 1000. In London also the death-rate was 16·0 per 1000 and was equal to the average rate in the 75 other large towns. The lowest death-rates in these towns were 5·1 in Willesden, 7·0 in Handsworth (Staffs.), 7·1 in Hastings, 7·3 in Newport (Mon.), 7·7 in Hornsey, 8·5 in Leyton, and 9·7 in Tottenham and in Devonport; while the highest rates were 20·6 in Oldham, 20·7 in Sunderland, 20·9 in Birkenhead, 21·8 in Burnley, 22·0 in Manchester, 22·4 in Birmingham and in St. Helens, and 25·6 in Warrington. The 4697 deaths in these towns last week included 556 which were referred to the principal infectious diseases, against 640, 583, and 530 in the three preceding weeks; of these 556 deaths 215 resulted from whooping-cough, 199 from measles, 44 from diarrhœa, 42 from diphtheria, 34 from scarlet fever, 16 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases was registered last week in Hastings, Bournemouth, Southampton, Northampton, Devonport, Burton-on-Trent, Handsworth (Staffs.), Smethwick, Wigan, South Shields, or Newport (Mon.); among the other towns the highest death-rates from the principal infectious diseases were recorded in Walthamstow, Birmingham, Wallasey, Bootle, St. Helens, Warrington, Manchester, Salford, Burnley, Huddersfield, and Rhondda. The greatest proportional mortality from measles occurred in Hornsey, West Ham, Walthamstow, Brighton, Norwich, Wallasey, St. Helens, Burnley, Huddersfield, and Rhondda; from scarlet fever in Warrington; and from whooping-cough in Walsall, Birmingham, Leicester, Birkenhead, Wallasey, Bootle, Warrington, West Hartlepool, and Swansea. The mortality from diphtheria, from "fever," and from diarrhœa was not excessive in any of the large towns. Of the six fatal cases of small-pox registered in these towns last week two belonged to Manchester and one each to London, Nottingham, Gateshead, and Tynemouth. The number of small-pox cases remaining under treatment in the Metropolitan Asylums hospitals, which had been 126, 134, and 144 on the three preceding Saturdays, had declined again to 123 on Saturday last, April 23rd; 23 new cases were admitted during the week, against 42, 25, and 37 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 1543, against 1570, 1505, and 1523 at the end of the three preceding weeks; 210 new cases were admitted during the week, against 153, 141, and 172 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 370, 333, and 295 in the three preceding weeks, further declined last week to 254 and were 29 below the number in the corresponding period of last year. The causes of 47, or 1·0 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Bradford, Leeds, Hull, Newcastle-on-Tyne, and in 45 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Blackburn, Rotherham, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·6, 20·3, and 20·9 per 1000 in the three preceding weeks, further rose to 21·0 per 1000 during the week ending April 23rd and was 5·0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·0 in Leith and 17·8 in Edinburgh to 25·8 in Dundee and 26·2 in Perth. The 695 deaths in these towns included 29 from whooping-cough, 26 from measles, 11 from diarrhœa, five from "fever," four from scarlet fever, three from small-pox, and one from diphtheria. In all, 79 deaths resulted from these principal infectious diseases last week, against 72, 57, and 65 in the three preceding weeks. These 79 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 per 1000 in excess of the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 23, 19, and 20 in the three preceding weeks, rose again last week to 29, of which seven were registered in Glasgow, seven in Aberdeen, six in Edinburgh, five in Dundee, and two in Greenock. The deaths from measles, which had been 23, 14, and 21 in the three preceding weeks, further rose to 26 last week and included 19 in Glasgow, three in Edinburgh, and three in Dundee. The fatal cases of diarrhœa, which had been nine, seven, and 15 in the three preceding weeks, declined again last week to 11, of which six occurred in Glasgow, and three in Dundee. The deaths referred to different forms of "fever," which had been four, three, and four in the three preceding weeks, further rose to five last week and included three in Glasgow. The fatal cases of scarlet fever, which had been five, two, and one in the three preceding weeks, rose again last week to four, of which three were recorded in Glasgow. The deaths from small-pox, which had been five, seven, and three in the three preceding weeks, were again three last week, and included two in Glasgow and one in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 157, 138, and 152 in the three preceding weeks, declined again last week to 115, and were 14 below the number in the corresponding period of last year. The causes of 20, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·5, 29·7, and 24·4 per 1000 in the three preceding weeks, further declined to 23·3 per 1000 during the week ending April 23rd. During the past four weeks the death-rate has averaged 26·5 per 1000, the rates during the same period being 17·5 in London and 18·9 in Edinburgh. The 169 deaths of persons belonging to Dublin registered during the week under notice showed a decline of eight from the number in the preceding week and included ten which were referred to the principal infectious diseases, against 20, 19, and 17 in the three preceding weeks; of these, five resulted from whooping-cough, three from measles, one from diphtheria, and one from diarrhœa, but not any from small-pox, from scarlet fever, or from "fever." These ten deaths were equal to an annual rate of 1·4 per 1000, the death-rates last week from the principal infectious

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MARCH, 1904.

* Including membranous croup.

diseases being 1·8 in London and 1·7 in Edinburgh. The fatal cases of measles, which had been four in each of the three preceding weeks, declined last week to three. The five deaths from whooping cough showed a decline of six from the number in the preceding week. The 169 deaths in Dublin last week included 29 of children under one year of age and 46 of persons aged 60 years and upwards; the deaths of infants showed a considerable decline, while those of elderly persons were slightly in excess of the number in the preceding week. Seven inquest cases and four deaths from violence were registered, and 67, or nearly two-fifths, of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1904.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·9 per 1000 of the population, estimated to be 4,649,088 persons in the middle of the year. In the three preceding months the rates had been 5·4, 5·1, and 4·8 per 1000 respectively. The rates were considerably below the average in Chelsea, the City of Westminster, Hampstead, Islington, and Stoke Newington; while they showed the largest excess in St. Pancras, Hackney, Bethnal Green, Stepney, Poplar, and Bermondsey. The prevalence of small-pox during March showed a very marked increase as compared with that recorded in other recent months; the greatest proportional prevalence of this disease was recorded in Hackney, Holborn, Bethnal Green, Stepney, Poplar, Southwark, and Battersea. The Metropolitan Asylums hospitals contained 126 small-pox patients at the end of last month, against 26, 21, and 31 at the end of the three preceding months; the weekly admissions averaged 31, against four, four, and six in the three preceding months. Scarlet fever was proportionally more prevalent last month than it had been during the preceding month. Among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in St. Pancras, Finsbury, Stepney, Camberwell, Deptford, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 1606, 1626, and 1560 at the end of the three preceding months, had further declined to 1546 at the end of last month; the weekly admissions averaged 160, against 168, 182, and 153 in the three preceding months. The prevalence of diphtheria, which had shown no appreciable variation during the four preceding months, had slightly decreased during March; this disease was proportionally most prevalent in St. Pancras, Hackney, Bethnal Green, Poplar, and Bermondsey, The Metropolitan Asylums hospitals contained 786 diphtheria patients at the end of last month, against 734, 752, and 782 at the end of the three preceding months; the weekly admissions averaged 94, against 104, 97, and 107 in the three preceding months. Enteric fever, which had shown a declining prevalence in the three preceding months, further diminished last month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Hammersmith, Holborn, the City of London, Shoreditch, Bethnal Green, and Greenwich. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 246 166, and 125 at the end of the three preceding months, had further decreased to 86 at the end of last month; the weekly admissions averaged 11, against 30, 16. and 15 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Bethnal Green, Southwark. Bermondsey, and Battersea. The 35 cases of puerperal fever notified during the month included three in Hackney and in Deptford, and two each in Paddington, Kensington, Fulham, St Pancras, Holborn, Bethnal Green, Poplar, Southwark, Wandsworth, and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending April 2nd the deaths of 8158 persons belonging to London were registered, equal to an annual rate of 18·3 per 1000; in the three preceding months the rates had been 17·2, 18·2, and 16·7 per 1000. The lowest death-rates in London last month were 10·7 in Hampstead, 12·5 in Lewisham, 13 7 in Stoke Newington, 14·3 in Woolwich, 14·7 in Fulham, 15·3 in Wandsworth, and 15·7 in Hackney; while the highest rates were 21·6 in Stepney, 23·2 in Finsbury, 23·3 in Southwark, 23 5 in Holborn and in the City of London, and 23 6 in Poplar. The 8158 deaths from all causes in London last month included 825 which were referred to the principal infectious diseases; of these, six resulted from small-pox, 337 from measles, 21 from scarlet fever, 85 from diphtheria, 270 from whooping-cough, 14 from enteric fever, and 92 from diarrhœa. The lowest death-rates from these diseases were recorded in the City of Westminster, Hampstead, Stoke Newington, the City of London, Wandsworth, and Woolwich; while they caused the highest death rates in Hammersmith, Shoreditch, Stepney, Poplar, Southwark, and Bermondsey. Of the six fatal cases of small-pox registered last month four belonged to Bethnal Green and one each to Holborn and Poplar. The 337 deaths from measles were slightly in excess of the average number in the corresponding periods of the ten preceding years, 1894–1903; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Hammersmith, St. Pancras, Holborn, Southwark, and Bermondsey. There were only 21 fatal cases of scarlet fever last month, against an average of 54 in the corresponding periods of the ten preceding years; of these 21 deaths, four occurred in St. Pancras, four in Bermondsey, two in Bethnal Green, and two in Stepney. The 85 fatal cases of diphtheria showed a decrease of 100 from the corrected average number; this disease was proportionally most fatal in Paddington, Hackney, Bethnal Green, Stepney, Poplar, and Southwark. The 270 deaths from whooping-cough were slightly below the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs the greatest proportional mortality from whooping-cough was recorded in Shoreditch, Stepney, Poplar, Bermondsey, Battersea, and Greenwich. The fatal cases of enteric fever numbered 14 last month, against an average of 41 in the corrresponding periods of the ten preceding years; three cases belonged to Southwark and two each to Hackney and Lambeth. The 92 deaths from diarrhœa were 27 in excess of the corrected average number; this disease was proportionally most fatal in Kensington, Fulham, Shoreditch, Stepney, Poplar, Bermondsey, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 17 per cent. below the average

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 143 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Islington, Wandsworth, Deptford, and Woolwich; and the highest rates in Paddington, Hammersmith, Shoreditch, Stepney, Southwark, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: P. E Maitland to the *Caledonia* and G T. Broatch to the *Challenger* Staff Surgeon O. M. Beadnell to the *Erebus*. Surgeon W. P. Yetts to the *Challenger*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel F B. Maclean takes over charge of the troops and Station Hospital at Canterbury. Major W. E. Hardy is posted to the Station Hospital, Shorncliffe, for duty. Lieutenant Colonel R. H. Moore and Major H. N. Thompson, D S.O., join at Aldershot for duty and are posted to the Cambridge Hospital.

The following officers have been appointed to the command of station hospitals for the summer season: Captain Powell, Lower Topa; Captain J F. Martin, Upper Topa; Captain W Beyts, Solan; Major G. T. Rawnsley, Kuldannah; Captain E. W. Siberry, Thobba; Captain P. McKessack, Khanspur and Ghora Dakka; Lieutenant P. Davidson, Kalabagh; Major C. J Holmes, Cherat; and Lieutenant S. M. W. Meadows, Khaira Gali.

Lieutenant-Colonel John Hoysted (retired) has been selected for duty with troops and appointed to Norwich.

The undermentioned Lieutenants, from the Seconded List, to be Lieutenants (dated April 5th, 1904): R. M. Ranking and F. H. Noke. Lieutenant G. W. G. Hughes is seconded for service with the Egyptian Army (dated April 7th, 1904). Lieutenant G. W. Smith resigns his commission (dated April 23rd, 1904).

Royal Army Medical Corps (Militia).

2nd South-Eastern District Company: Lieutenant H. V. Craster resigns his commission (dated April 23rd, 1904).

Imperial Yeomanry.

Derbyshire: Surgeon-Lieutenant R. M. Wilson to be Surgeon-Captain (dated April 23rd, 1904). The North of Ireland: Edward Charles Thompson to be Surgeon-Major (dated April 16th, 1904).

Army Medical Reserve of Officers.

Surgeon-Captain D. Todd to be Surgeon-Major (dated April 13th, 1904).

Volunteer Corps.

Rifle: 1st Bucks: Brigade-Surgeon-Lieutenant-Colonel W. H. Bull is seconded whilst holding the appointment of Senior Medical Officer of the Home Counties Volunteer Infantry Brigade (dated April 23rd, 1904). 2nd Volunteer Battalion the Loyal North Lancashire Regiment: The undermentioned gentlemen to be Surgeon-Lieutenants:—James Wood (dated April 23rd, 1904) and Frank Robinson (dated April 23rd, 1904).

Royal Army Medical Corps (Volunteers).

The London Companies: The following is substituted for that which appeared in the *London Gazette* of April 15th:—Major V. Matthews to be Lieutenant-Colonel and to command under paragraph 55A Volunteer Regulations (dated April 9th, 1904).

Volunteer Officers' Decoration.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officer of the Volunteer force:—*Scottish District*: *Rifle*: 1st (Inverness-shire Highland) Volunteer Battalion the Queen's Own Cameron Highlanders: Brigade-Surgeon-Lieutenant-Colonel Ogilvie Grant, retired.

Scottish Volunteer Ambulance Trophy.

The first annual competition for the new ambulance trophy presented by the Scottish Volunteer Medical Officers' Association will take place at the headquarters of the 1st L R V., West Prince-street, Glasgow, on Saturday, May 14th, at one o'clock. The need of a Scottish competition has arisen from the obvious difficulties which prevent many teams presenting themselves in London for examination in the already existing national competition. The trophy is valued at 300 guineas and the examiners appointed are Lieutenant-Colonel R. J. Geddes, D.S.O., R.A.M.C., Major C. C. Fleming, D.S.O., R.A.M.C., Brigade-Surgeon-Lieutenant-Colonel A. D. Webster, 1st L.V.I., Edinburgh, Surgeon-Lieutenant-Colonel A. Napier, 3rd L R.V., Glasgow, Honorary Staff-Surgeon J. McIntyre, R.N.V.R, Surgeon-Major J. Mill, A.M.R., Leith, and Major McGregor Robertson, R A.M.C.V., Glasgow. The competing teams represent practically all branches of the volunteer services and hail from as far north as Inverness. The competition will be presided over by Director-General Sir William Taylor, in the presence of Colonel the Marquis of Breadalbane and the Marquis of Graham, commanding officer of the Clyde Division of the Naval Volunteers. Lord Provost Sir John and Lady Primrose also intend to be present and the winning team will have the trophy handed to it by her Grace the Duchess of Montrose who has consented to perform this ceremony. The organisation of this competition has been largely the work of the honorary secretary of the association, Captain R T. Halliday, R A.M.C.V., Glasgow, who with Lieutenant Wright Thomson of the same corps is responsible for the general arrangements. On the same evening the annual dinner of the association will take place in the Windsor Hotel under the chairmanship of the President, Surgeon-Major Quintin Chalmers, H.L.I. Brigade Bearer Company, and Lord Breadalbane, Sir William Taylor, and Sir John Primrose will be the chief guests.

The Projected War Office Reform.

The Army Medical Service is not the only branch of the service affected by the new scheme set forth in the reports of Lord Esher's Reconstruction Committee. It is contended on the part of the Auxiliary Forces that the reversal by that committee of Mr. Brodrick's ruling that the office of the Inspector-General of these forces was to be a separate one under the Commander-in-Chief has altogether altered the basis of their position at the War Office. The Government, without waiting for the report of the Royal Commission on the Auxiliary Forces now sitting, has apparently adopted the arrangement recommended by Lord Esher's committee and the Auxiliary Forces are to be placed, as in the case of the Army Medical Service, under the adjutant-general as a branch of his office. This has naturally given rise to a good deal of difficulty and discussion. A correspondent of the *Standard*, in an able article on "War Office Reform" which appeared in that journal on April 25th, deals with the scheme which has been proposed by Lord Esher and his colleagues as a whole and from this article we extract the following remarks regarding the Army Medical Service:—

> The third part of the report contains, as the committee observe, no new principle but is descriptive and explanatory of the nature and duties of offices already created and of principles already accepted. A noticeable feature of it is the proposal to place the Army Medical Department under the Adjutant-General. The position and status of the staff of this department have long been a source of trouble and friction. Under the Army Council system now inaugurated the head of the department must clearly either be on the Army Council as an extra military member or must "report to" one or other of the military members. For strong reasons, the committee reject the first alternative and select the Adjutant-General as the natural superior of the medical staff. The staff of this department having only recently been elevated into a Royal corps and placed directly under the Commander-in Chief it is to be feared that the change now proposed will not be altogether acceptable to this vitally important branch of the Service; but it is difficult to see what other alternative is compatible with the new organisation of the Military Departments of the War Office.

The writer of the article in question then goes on to say that a similar difficulty arises with regard to the Auxiliary Forces as to the position of their representative at the War Office.

Volunteer Ambulance School of Instruction.

Surgeon-General Sir William Taylor, K.C.B., K.H.P., Director-General of the Army Medical Department, has accepted the invitation of Brigade Surgeon-Lieutenant-Colonel P. B. Giles and officers of the Volunteer Ambulance School of Instruction to be present at the annual dinner which will take place at the Trocadéro Restaurant, Piccadilly Circus, London, W., on Thursday, May 12th. Among others who have signified their intention of being present are: Sir Robert Ball, F.R.S., Mr. Jonathan Hutchinson, F.R.S., Colonel A. T. Sloggett, C.M.G., R.A.M.C., Colonel G. W. Robinson, R.A.M.C., Colonel E. M. Wilson, C.B., C.M.G., D.S.O., R.A.M.C., Colonel E. C. Stevenson, 3rd City of London V.R.C., and Dr. J. Galloway.

The War in the Far East.

The *Daily Graphic* says: "The services of Miss McGee, the American lady doctor who, with a staff of eight nurses, has volunteered to assist the Japanese medical staff at the front, have been accepted and the party has already arrived at Yokohama where they received a most cordial welcome. Miss McGee and her companions, after a short stay in the Japanese capital, will be detailed to a hospital ship."

Surgeon Francis F. Lobb, R.N., at present attached to the Plymouth division of the Royal Marine Light Infantry, has received the African general service medal, with clasp "Aro, 1901–1902." Colonel-Commandant A. D. Corbet, C.B., made the presentation at the morning parade at the Royal Marine Barracks, Stonehouse, on April 22nd.

GENERAL LYING-IN HOSPITAL, YORK-ROAD, LAMBETH, LONDON, S.E.—The entertainment referred to in THE LANCET of April 16th, p. 1047, has been postponed from May 26th until some time in the autumn, probably October, but the bazaar on July 8th and 9th will be held as announced.

THE MEDICAL DIPLOMATES SOCIETY OF LONDON.—At the last meeting of the London Licentiates and Members Society, which was held at 20, Hanover-square on April 19th, under the presidency of Dr. F. J. Smith, it was agreed to alter the name of the society to the Medical Diplomates Society of London.

Correspondence.

"Audi alteram partem."

ON SYPHONAGE IN THE LARGE INTESTINE.

To the Editors of THE LANCET.

SIRS,—May I point out to Dr. R. W. Leftwich that experiments worked out with a syphon of garden hose with glass insertions and treacle, fully described in his book, "prove" nothing as regards the action of the human colon and do not justify the treatment of patients as syphons. Before placing his patients in the upright posture to secure a syphonage effect he must first render the contents of the great intestine "capable of flowing" (which will be necessary in over 90 per cent. of cases); he must render the walls of the colon rigid, which can be done only by producing a negati [illegible] ity, which can be done by inv [illegible] nnot be produced by either [illegible] of the colon, the one shorte [illegible] ishes its calibre, but neither can act in the opposite way, as Dr. Leftwich believes it can. A negative pressure in the cæcum is a product of Dr. Leftwich's imagination. The muscular coats are, as I have already shown, more than sufficient to propel the contents of the colon and readily hypertrophy when there is a localised obstruction to be overcome. As for the "daily morning evacuation" being the result of syphonage, how does Dr. Leftwich account for the fact that most domestic animals (especially noticeable amongst cows) always evacuate when they rise from a period of rest?

I am, Sirs, yours faithfully,
ARTHUR KEITH.
April 23rd, 1904.

BILHARZIA HÆMATOBIA.

To the Editors of THE LANCET.

SIRS,—*Re* bilharzia hæmatobia, as I have been practising here for the last ten or 12 years and have necessarily, therefore, come in contact with very many cases of the above I take the liberty of answering Mr. E. H. Worth's question as regards treatment published in THE LANCET of Feb. 27th (p. 611). My experience leads me to believe that treatment has very little, if any, effect upon the course of the disease which in temperate persons is almost invariably mild and favourable. Iron alum is, I think, the best iron preparation if the hæmaturia is excessive, or the tinctura ferri perchloridi, while for the burning at the meatus during micturition my favourite drug is potassium citrate, which also presumably assists in preventing the formation of calculi These last are occasionally a troublesome complication but are, in my experience, invariably of small size and are only brought under the notice of the practitioner by becoming impacted in the urethra or by causing an attack of renal colic.

I am, Sirs, yours faithfully,
F. T. AUDEN, M.D. Edin.
Rustenburg, Transvaal, March 26th, 1904

A PROBABLE FRACTURE OF THE BASE OF THE SKULL WITH RECOVERY.

To the Editors of THE LANCET.

SIRS,—The following case may be of some interest. The accident occurred to a friend of mine who was coasting down a steep hill on his bicycle when, owing to a sudden swerve while he was going very fast, he collided with a wooden fence, completely injuring the front wheel and forks and also receiving a cut over the right parietal eminence from which there was considerable hæmorrhage. He was slightly unconscious for a few moments but managed with slight assistance to walk afterwards. Later there were some hæmorrhage from the right external meatus and considerable pain about the right tympanum when coughing or blowing his nose, also complete loss of hearing by the right ear and a considerable amount of blood came from the nose when it was blown. This condition continued for about 12 hours and then the hæmorrhage ceased but for three days the patient was quite deaf on the right side and still had pain about the right tympanum and a hissing noise when he blew his nose. When walking on the fourth day he noticed a slight creaking noise about his right ear. This disappeared after a while and his hearing after a week was much improved. He was never laid up.

I am, Sirs, yours faithfully,
AJAX.
April 23rd, 1904.

THE VISION OF MYOPES.

To the Editors of THE LANCET.

SIRS,—With reference to the correspondence on the above subject which appeared in THE LANCET during October, 1903, when some methods of temporarily improving the vision of myopes were discussed, I beg to call attention to a little dodge which I have discovered with the same object. In the centre of my watch glass there is a little plano-concave disc with which many watch glasses are made and I find that by opening the glass of the watch and looking through this little concave portion it acts as a lens especially suitable to the myopic eye. Of course, this is merely an emergency dodge, but it is far better than making two pin-holes in a piece of paper or cardboard to get a binocular effect or looking into a small convex mirror wherein, although objects are clearly reflected to the myopic eye, the reversal of words on shop fronts, and so forth, is especially noticeable.

I am, Sirs, yours faithfully,
MYOPE.
London, April 27th, 1904

THE GERMAN SURGICAL CONGRESS.[1]

(FROM OUR BERLIN CORRESPONDENT.)

THE German Surgical Congress met in Berlin from April 6th to 9th, Professor BRAUN of Göttingen being in the chair. After the conclusion of the introductory proceedings Professor Braun made a sympathetic allusion to the eight deceased members and especially to Professor Gussenbauer of Vienna, the president of the Congress held in 1901. The Librarian (Professor FISCHER) reported that the new catalogue was now at the disposal of the members and on sale, the library containing 3756 books, 2254 volumes of journals, and 8862 reprints of articles.

Operations on the Blood vessels.

Professor KORTE (Berlin) showed a boy, 13 years of age, who as a sequel to a knife wound suffered from an arterio-venous aneurysm of the popliteal vessels. Professor Körte under Esmarch's ischæmia cut down on the tumour, broke down the adhesions, and sutured the wounds of the vessels. Primary union and complete cure were obtained.

Dr. RIESE (Britz) reported a similar case of aneurysm in a boy, aged 11 years, where a piece of bone two inches long was found in the wound of the popliteal artery.

Carcinoma.

Professor PETERSEN (Heidelberg) reported some cases of late relapses of cancer. In a case of cancer of the tongue operated on by the thermo-cautery a relapse appeared after 19 years and was treated a second time by the same procedure; no enlargement of the glands was present on either occasion. In another instance of cancer of the mamma where radical extirpation had been performed in 1889, local relapses were observed every third year and operated on, so that five operations—the last one in 1903—took place. At present the woman was in good health.

Dr. PERTHES (Leipsic) read a paper on the treatment of cancroids by the Roentgen rays. In 12 out of 13 cases a complete cure, and in the last one a considerable improvement, was obtained. As the majority of the cases were of comparatively recent date there might possibly be relapses. In three cases of cancroid of the lips the result was favourable, in other instances unfavourable, and so were some cases of cancer of the mamma. Dr. Perthes explained that the action of the rays was somewhat superficial—namely, only for a depth of about an inch. He was of opinion that the rays might have a specific action on the carcinomatous tissue, their influence on the metastatic glands being obvious.

---

[1] For this report we wish to tender our thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our correspondent.—ED. L.

Professor **LASSAR** (Berlin) in the discussion concurred in the opinion of Dr. Perthes and showed a number of patients who had either recovered or been benefited. He mentioned that cancroids sometimes disappeared under arsenical treatment.

Operations on the Gall bladder.

Professor **KEHR** (Halberstadt) reported that he had up to the present time performed 911 operations on the gall-bladder and among them there were 11 remarkable ones in which he had directly joined the gall-bladder with the stomach (cystogastrostomy); in one of these 11 cases a retention cyst of the pancreas was present which was led into the gall-bladder so that after the operation the bile and the pancreatic juice were discharged into the stomach. One case was a hepato-cholangio-enterostomy—i e., a direct union of the bile passages to the duodenum; in another case of aneurysm of the hepatic artery this vessel was tied.

Professor **RIEDEL** (Jena) recommended making the ductus choledochus accessible by a large flap and raising the liver. By this procedure more complicated measures might be avoided.

Professor **PAYR** (Graz) spoke of Kocher's method of freeing the duodenum in the course of which he had once observed fatal hæmorrhage

Professor **HAIDENHAIN** (Worms) showed an instrument by which after the opening of the gall-bladder the calculi might be removed.

Dr. **HABERER** (Vienna) described experiments relative to the possible formation of a new gall-bladder after cholecystotomy.

Professor **KRASKE** (Freiburg) drew attention to the difficulty of removing calculi situated in the end of the ductus choledochus. A direct incision on Vater's diverticulum might be dangerous owing to the fact that eventually a pancreatic fistula might arise. In every instance of diverticulo-duodenostomy accurate sutures and packing with gauze were indispensable.

Dr. **PELS-LEUSDEN** (Berlin) showed a patient in whom, after a cholecystostomy, papillomatous growths developed in the gall-bladder; the patient made a good recovery, but a small fistula persisted from which some years afterwards new papillomata were removed.

Dr. **MEYER** (Brussels) discussed the resection of parts of the abdominal wall and of the ligamentum teres for hepatoptosis which as a rule was associated with general enteroptosis.

Dr. **GRASER** (Erlangen) discussed traumatic rupture of the liver. In the course of a laparotomy for abdominal pain he found a large cavity in the liver filled with pus and containing some small pieces and one large piece of liver. The etiology of the cavity was somewhat obscure; it was, however, ascertained that the patient, one and a half years before, had fallen from a height of 16 feet without feeling any considerable pain. Six months later pain began without fever. In another case of abscess of the liver after perityphlitis the infection had very likely arisen from the portal vein.

Traumatic Lesions of the Abdominal Organs.

Dr. **RIESE** showed a patient who had received a bullet wound of the liver, stomach, kidney, and spleen. An operation was speedily performed, and recovery ensued. Dr. Riese recommended the use of catgut for sutures of the liver.

Dr. **BRENTANO** (Berlin) reported the case of a patient with a bullet wound of the abdomen who had suddenly died after seven days' illness. At the necropsy a retroperitoneal lesion of the abdominal aorta with enormous hæmorrhage was found.

Dr **PELS LEUSDEN** showed a girl who had received a gunshot wound, the thorax and the abdominal cavity being traversed and the diaphragm and the spleen lacerated Notwithstanding this grave injury recovery ensued. By means of radiography about 30 shots could still be seen.

Dr **THOLE** gave a report of his researches on the blood of the portal vein which, according to him, was sterile, so that the way of infection from the duodenum was probably not through the blood-vessels but through the bile.

Dr **VON FRISCH** (Vienna) said that he had observed in a case of abdominal gunshot wound, where the stomach was perforated, that the posterior opening was smaller than the anterior one and found this fact to be confirmed by numerous experiments on animals.

Connexion between Diseases of the Gall-bladder and Pancreatitis.

Professor **KORTE** spoke on the connexion between diseases of the gall-bladder and pancreatitis. He had seen seven cases of acute pancreatitis together with cholelithiasis, of which four were cases of calculi of the ductus choledochus, one was a case of 900 calculi of the gall-bladder, one of cholecystitis, and one of cholangitis; three patients recovered and four died. The symptoms of these complicated and grave cases were rather obscure.

(To be continued.)

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

THE MANCHESTER AND SALFORD PROVIDENT DISPENSARIES ASSOCIATION.

WHILE dealing with the prevalence of hospital abuse at Manchester in a series of special articles some years ago the Manchester and Salford Provident Dispensaries Association also came in for a large share of criticism.[1] Cases were given of the gross abuse proving that what was intended for the poor was being utilised by persons who could well afford to pay proper medical fees. Complaints were also made that leaflets and other methods of advertising these dispensaries were employed, much to the detriment of the interests of the private practitioner. It is true that the practitioners themselves were somewhat to blame, for many new-comers had commenced their careers under the patronage of the Provident Dispensaries Association. Being anxious to render themselves popular and to increase the number of members on their list so as to lay the foundations of a practice, these new arrivals were not so likely to endeavour to prevent abuse. Originally the idea was, on the contrary, to constitute a district provident and charity organisation society of Manchester and Salford and thus to combine the work of preventing abuse of charity with that of organising a provident dispensary. For this purpose patients were divided into four categories. Persons absolutely devoid of any resources were to be referred to the Poor-law. The second category consisted of very poor people and they were to be sent to the hospitals. This meant in the case of single persons those who could not earn more than 15*s.* a week and in the case of married couples a limit of 21*s.* Above this figure the third category was reached and this consisted of people still too poor to pay medical fees but yet earning enough to insure against sickness by paying a penny per week. Should such persons have failed to take this precaution before they fell ill they might nevertheless join a provident dispensary and obtain immediate medical attendance on paying an entrance fee of 5*s.* The fourth category was composed of the rest of the public, that is, persons who on inquiry were considered capable of paying medical fees. Such were the principles which it was intended should govern the provident dispensaries. They soon broke down in practice.

Instead of maintaining the classification just described it was thought that the interests of the medical profession would be sufficiently guaranteed by allowing medical officers of the dispensaries to sit on the boards of management. In spite of this, however, so much abuse arose that the 17 medical men who formed the first staff of the dispensary resigned and thereupon two new medical men were imported from outside and were given fixed salaries. With their aid the dispensary grew and branch establishments were opened in the outskirts, but the original scheme for reform and the prevention of abuse was more than ever consigned to pigeon-holes where are kept records of a forgotten past. Not only were abuses allowed but the medical officers were obviously sweated by the dispensaries and in 1895 they met and protested, pointing out that during the year the subscribers had paid £4422 and the medical officers had only received £2612 It is true that answer was made to this, the management throwing the whole blame for abuse on the medical officers themselves [2]

All this, however, is ancient history. The profession is better organised now, especially in the Manchester district.

---

[2] See THE LANCET, Jan. 23rd, 1897, p. 276.

It is also better supported by the General Medical Council in matters of this description. Institutions like these provident dispensaries should therefore be particularly careful not to re-awaken the old grievances and complaints. Nevertheless, new, as well as the old, grievances have arisen involving a whole series of side issues and sociological problems. It has been explained that the provident dispensaries are supposed to enrol only poor people who cannot pay medical fees and that they must subscribe a penny per week—*that is, 4s 4d.* per annum. *It has also* been very generally believed that when the State or a municipality employs labour it is in honour bound to set a good example and to pay the highest current rate of wages. Therefore it was to be expected that persons employed by the Manchester corporation would on their side pay their medical attendants at least as well as do the other members of their class. To the credit of one of the bodies of workmen concerned it must be recognised that they never *thought of acting otherwise. The Manchester corporation servants engaged in the cleansing department and* the tramway employés, who number some thousands, followed the example of other large bodies of workmen and sought to join a sick benefit society. There is a Vehicle and Tramway Workers Association which is a trade union and has branches all over the country. Representations were made on behalf of the Manchester Medical Guild to the secretary of the Salford branch of the Tramway Workers Association and he approved of the position taken up by the organised members of the medical profession. It was pointed out that in Salford some medical practitioners had applied for the post of medical officer to the Salford tramway workers and had offered to do the work for a subscription of only 3*s*. 6*d*. or 3*s*. per member. The tramway workers, however, would not entertain such proposals. They preferred to engage a member of the Medical Guild, paying him the established rate accepted by the Guild of 4*s*. 4*d*. per annum, rather than to save a little money by employing a practitioner who was acting against the interests and the policy of the members of his profession.

In the face of all these circumstances it is easy to imagine the indignation aroused by a rumour that efforts had been made to induce all, or at least a large number, of workers engaged by the corporation to join the dispensaries at a reduced tariff. The secretary of the provident dispensaries was said to have addressed midnight meetings of tramway servants. Though ordinary poverty-stricken people had to pay 4*s*. 4*d*. a year he was reported to have offered to accept as members the comparatively well-paid municipal employés for only 3*s*. 6*d*. per head. At the same time the chairman of the tramway committee was boasting that the receipts made by the corporation tramways had exceeded £16,000 in one single week and that this was a record for Great Britain. In that case, why should the workers engaged in so exceptionally prosperous an enterprise be unable to pay medical fees? Were medical men to attend on charitable terms the servants of the ratepayers? On what ground had they any right to claim medical services at reduced rates? The Manchester Medical Guild discussed this matter on several occasions and correspondence ensued. The upshot was that first the general secretary of the provident dispensaries denied that he had addressed a meeting of tramway workers. The council of the Medical Guild then attempted to obtain evidence, though it was a difficult matter, as considerable time had elapsed since the holding of such meetings. Nevertheless, several men were found who swore an affidavit before a commissioner for oaths that they were present at a meeting held at Holt Town cleansing depôt dining-room on March 28th, 1903, when about 200 men were present. Mr. Stanley Jones, the general secretary *of the provident dispensaries, is reported by the Medical Guild Quarterly* on the evidence of these witnesses to have addressed the men and to have pointed out to them the advantages of joining the dispensaries. The handbill con- [illegible]

regarded as "touting and canvassing" and would in consequence, if reported to the General Medical Council, be regarded as "infamous" in the professional sense because the medical officers of the dispensaries would profit by the touting practised by their secretary. Thereupon the medical officers of the Pendleton branch of the dispensaries passed and forwarded resolutions to the general committee of the Provident Dispensaries Association complaining of the action of the secretary as it compromised their position and exposed them to a reprimand from the General Medical Council. Perhaps after this warning *the secretary of the dispensaries will be more reserved.* But, nevertheless, a large number of tramway workers in the service of the Manchester corporation have been induced to join the dispensaries at 3*s*. 6*d*. a year and the medical staff only receives a little more than half this sum for attending to them when they are ill. So there are two causes of complaint: first, that touting has been practised; and secondly, that there is no reason to offer what amounts to charity when the recipients are the employés *engaged on what has proved to be an exceptionally prosperous municipal enterprise. Municipalities are, on* the contrary, bound to do their utmost to prevent sweating but because in this case the victims of the sweating system are professional men instead of members of the artisan class is no concern to be manifested for their welfare? "Sweating" is subcontracting and here are a lay secretary and committee contracting to supply medical attendance at 3*s*. 6*d*. per annum. But being themselves incapable of supplying this medical attendance they subcontract with medical men to attend the tramway servants and others. This is a subcontract and this constitutes sweating in the technical sense of the term, the first contractor having an opportunity of "sweating" a profit out of the second or sub-contract. To what extent this sweating is practised in this particular instance still remains to be proved but in the meanwhile the following figures are suggestive. They were submitted at the twenty-seventh annual meeting of the Hulme branch of the Manchester and Salford Provident Dispensaries Association. The subscription of members during the year amounted to £637 4*s* 2*d*. and out of this only £376 9*s*. 10*d*. were paid to the *medical staff.* The receipts of the year exceeded the expenditure by £50 19*s*. 3*d*. and the branch had a reserve fund of £521 10*s*. 4*d*. There were 3371 members and during the year 34,193 prescriptions had been made up for them. To yield the profit and to pile up a reserve fund the medical officers, it will be seen by these figures, had to give prescrptions *at less than 3d. each.* This looks very like sweating. Not the working classes alone but all classes of the community have joined in the desire that the sweating system should be abolished and there is a strong *feeling that in this matter the State* and the municipalities should give a good example. It seems as if this has not been done in Manchester in so far at least as the interests of the medical profession are concerned.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Infantile Mortality in Liverpool: Artificial Foods and the Sterilised Milk supply.

IN a report on the work of the health committee's depôts for the preparation of humanised milk for the use of infants Dr. E W. Hope, the medical officer of health, refers at length to the high rate of mortality among infants below 12 months of age. Last year the death-rate of Liverpool was the lowest ever recorded, yet infantile mortality was 159 out of every 1000 born The average for the last three years was 178 out of every 1000 born. The most frequent causes contributing to this high infantile mortality were atrophy, diarrhœa, and convulsions, all pointing to the assumption that from some *reason or other* nutrition was interfered with and that the infants were unable to live upon the food given to them. The loss of life from diarrhœa and kindred ailments is greatest in the summer and autumn months and Dr. Hope's careful observations, extending over several years, showed that the deaths of infants wholly or partially fed during those seasons on artificial foods were 15 times as great as they were amongst an equal number of infants fed upon breast milk. As the age of the infants increased the death-rate among children fed on artificial foods diminished. The most discouraging feature was the want of maternal care and intelligence. The efforts of the health committee to insure a pure supply of cow's milk, the nearest approach to the infant's natural food, have been constant, but the problem of finding a complete substitute for the milk of a healthy mother has not been, and probably never will be, solved. The project of humanising the milk—that is to say, making it by the addition of milk-sugar, water, and cream as nearly as possible of the same chemical composition as the human milk and sterilising it—and adopting such methods as will enable the infant to receive this milk pure and without contamination was first introduced on a small scale at St. Helens and is now extensively carried out by means of distributing depôts in Liverpool. It was not claimed that the recent reduction in the rate of infantile mortality had been altogether brought about by the sterilised milk, yet it had undoubtedly played a part in the matter. From the date of the initiation of the scheme (early in 1901) to Dec. 31st, 1903, 6295 infants had been fed upon this milk, supplied either at the depôts or through dairies, the average age at the commencement of the feeding being three and a half months In the great majority of instances the infants thrived, increasing in weight and remaining healthy. Without attempting to draw too close deductions, the fact remains that out of 4453 infants coming very promiscuously to the depôts, at varied ages, and in conditions of health below the average, the mortality was 78 per 1000, as against 159 per 1000 for the whole city and from 88 to 118 for the best districts and from 212 to 215 for the worst. The figures are very remarkable and are clearly and strongly in favour of persevering with the supply of humanised milk. There are four depôts in the city where the milk is supplied—viz., Netherfield-road, Earle road, Cazneau-street, and Park-road, all situated at different quarters of the city. The milk is supplied in nine bottles in a basket, each bottle containing sufficient milk for one feed, according to the age of the child. When all the milk in one bottle is not used the remainder must not be warmed up again for the infant but a fresh bottle must be opened for the next meal. The milk will be found to be quite sufficient if given regularly. The person using the milk must guarantee to continue its use regularly during the needs of the child and to send for it at the stated hours. Should the milk not agree with the child the matter should be reported at once. Every person using the milk will be supplied with two teats which must be kept clean and taken to the depôt for inspection at least once a week. Extra teats will be charged for at the rate of 3*d.* each. Just before using each bottle should be placed unopened in a jug or basin of hot water and warmed to the proper temperature. The bottle should then be opened and the teat inserted. It is recommended that at first the infant should be fed every two hours during the day and every four hours during the night. After using the bottle should be thoroughly rinsed in cold water. If children are sent for the milk they must be warned not to tamper with the stoppers of the bottles. The cost of the full weekly supply is 1*s.* 6*d.*, payable in advance.

Health Students' Association.

At the opening meeting of the spring session of this association a lecture was delivered by Dr. Nathan Raw, physician to the Mill-road Infirmary, on the Prevention of Consumption in Large Cities. He drew special attention to the importance of diffusing knowledge on the subject among all classes of society and referred to the valuable teaching work done by the members of the association. One of the most important points touched on in the course of his interesting and instructive lecture was that tuberculosis was not by any means confined to the human race but that many domestic animals suffered from the disease and became centres of infection, the greatest harm resulting from the use of milk from infected cows. In this connexion he strongly supported the action of the Liverpool health committee in the establishment of sterilised milk depôts. Dr. Raw explained at some length the preventive measures which ought to be taken in nursing cases of phthisis in private houses and also alluded to the benefits of sanatoriums. He laid stress on the need of adequate provision for the treatment of advanced cases of the disease among the poor whose only refuge at present was the workhouse hospital. Dr. Raw was one of the pioneers in the movement for the establishment of the Liverpool sanatoriums. Questions were asked by several of those present to which the lecturer replied at length. The proceedings concluded with a cordial vote of thanks to Dr. Raw for his interesting address.

Royal Southern Hospital Nursing Institution.

At the annual meeting of the supporters of this institution held on April 20th, Dr. John Cameron, consulting physician to the Royal Southern Hospital, intimated his desire to retire from the position of chairman of the committee. Dr. Cameron has acted as chairman during the past 13 years and took a very active part in the inauguration of the nurses' home 24 years since; it is mainly due to him that so much useful work has been done in the past and that the institution has been so successful. The committee accepted Dr. Cameron's resignation with much regret and trusted that he would continue his connexion with the institution by accepting the office of president. Dr. Cameron is the doyen of the profession in Liverpool, his election as a member of the Liverpool Medical Institution dating so far back as the year 1839

New City Analyst.

Professor J. Campbell Brown, the professor of chemistry at the University of Liverpool, has resigned the post of public analyst of Liverpool and the health committee of the city council has recorded its best thanks for his valuable services during the past 31 years. Mr. Collingwood Williams is to be his successor, subject to the approval of the city council, at £850 per annum for salary and expenses. He will be required to analyse for the corporation 1800 samples taken for the purposes of the Sale of Food and Drugs Act; in excess of that number he will receive 8*s.* per sample.

April 26th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Meeting of the Sanitary Institute at Cardiff.

When the Sanitary Institute met at Manchester in 1902 it was suggested that sessional meetings might with advantage be held in districts outside London. The council of the institute accordingly arranged for a meeting in Manchester in February, 1903, and it was so successful that other meetings have since been held in Birmingham, in Leicester, and on April 23rd last in Cardiff. There was an audience at Cardiff of about 80, presided over by Mr. W. Whitaker, F.R S., the chairman of the institute council, and a discussion upon School Hygiene was opened by Dr. Edward Walford with an address a summary of which will be found at p. 1219 of our present issue. In the course of the discussion which followed Dr. Walford's address Dr. J. Howard-Jones of Newport said that many sanitary defects in school buildings were left unremedied because of the expense involved, but he pointed out that £1,250,000 sterling were expended annually upon the education of children under five years of age and this sum would not only be sufficient for the provision of better schools but there would be something left for higher education. Dr. D. R. Paterson urged the importance of providing properly ventilated schools, not only for the children, but for the sake of the teachers who could not work properly under bad conditions. He also pleaded for those children who were partially deaf and where the defect was remediable but where if left unremedied the child often drifted into the class of those mentally unfit. Dr. H Meredith Richards expressed the hope that school committees would see that the cubic space in non-provided schools was brought up to the standard required in provided schools. Mr. Herbert Jones drew attention to the large number of schools which were in use where the windows were in an utterly wrong position, compelling the children to twist themselves into unnatural postures, and Dr. J. Tatham Thompson endorsed the desirability of providing for the light to fall on the left side. He also deprecated the sending of children under five years of age to school, for educationally it was of no value and physically it was full of dangers. Miss Hurlbatt, the principal of Aberdare Hall, the women's hostel of Cardiff College, considered that the physical condition of many middle-class girls was woefully neglected. They came to the college with bad teeth and therefore impaired digestion, with bad eyesight and therefore headaches, and were quite indifferent to the advantages of being out in the open air. There was a low standard of vitality among many young girls which she thought might be remedied if they had more time to do absolutely nothing—to be, in fact, lazy. The chairman of the Glamorgan county council education committee (Dr. T. H. Morris) placed upon the Board of Education the responsibility for a great deal of the deficient sanitary condition of schools. The Board, he said, was a distinct brake to progress.

Small-pox in Swansea.

Swansea has been exceptionally free from small-pox for many months but there is now one case in the isolation hospital. The patient who was a stowaway was landed from a coasting vessel trading between Glasgow, Liverpool, and Swansea. As he was obviously ill he was taken from the ship to the workhouse infirmary where he remained two days.

Dangers of Celluloid Collars.

The danger of using celluloid wearing apparel was once [illegible] last week. A youth after lighting [illegible] lighted match which fell upon the [illegible] boy whose neck and hair were burned, though fortunately without any serious result.

Fixity of Tenure for Medical Officers of Health.

Dr. Hugh Jones, the medical officer of health of the Dolgelly rural district, has been appointed by the district council for an indefinite period instead of as on previous occasions for three years only. This course was taken by the council in response to a communication from the Local Government Board stating that the Board had had under consideration generally the question of the tenure of office of medical officers of health and that it would be prepared to consider favourably an application for its sanction to Dr. Jones's re-appointment as medical officer of health without limit of time. The same fixity of tenure of office has also been secured in Wales by the medical officers of health of Cardiff, Rhondda, and Pontypridd urban districts and Llandaff and Dinas Powis rural district.

Bristol Royal Hospital for Women and Children.

The annual meeting of the subscribers to this institution was held on April 23rd under the presidency of the Lord Mayor. The medical report stated that 676 children and 65 women had been admitted as in-patients during 1903, as compared with 685 children and 64 women during 1902. 3534 children and 2046 women had been treated in the out-patient department. The financial statement showed that the total ordinary income amounted to £4449, the expenditure being £4904. The total adverse balance of the hospital now amounts to £1308. The Ladies' Auxiliary Association, under the presidency of the Duchess of Beaufort, had raised £523 for the funds of the institution. The committee in its report refers sympathetically to the death of Dr. J. G. Swayne of Clifton who for many years was the consulting obstetric physician.

Notification of Phthisis.

The annual report of the Exeter health department, which was issued on April 22nd, states that during 1903 the voluntary notification of phthisis has been practically useless, as not one case was notified although the city council offered to pay the usual fee for notification and 67 deaths were registered from the disease during the year.

April 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Glasgow.

THE annual graduation ceremony at the University of Glasgow took place in the Bute Hall on April 18th. There was a very large attendance of students and the general public. Principal Story, the Vice-Chancellor, presided and performed the capping ceremony. The doctors of medicine (M.D.) numbered three and the bachelors of medicine and surgery (M.B, Ch.B) numbered six, including one lady. The following day (April 19th) was observed as Commemoration Day. This is a new feature of the academic life as far as Scotland is concerned, though not uncommon in England, the idea underlying the ceremony being to recall the names of great men associated with the past history of the University. The arrangements for the different functions were admirably carried out by a joint committee of the University Court, Senate, and General Council. The proceedings began in the morning with a short service in the Bute Hall conducted by Principal Story, assisted by the Rev. Professor Taylor, Edinburgh, and the Rev. Professor Herkless, St. Andrews. This was followed by an oration on "Joseph Black, M.D.," by Sir William Ramsay, K.C B., of University College, London. At the close of the address Principal Story, on behalf of the University, conferred the honorary degrees. Professor J. Glaister presented those receiving the degree of doctor of laws, among whom were the Hon. Joseph Hodges Choate, who at present fills the distinguished position of ambassador from the United States of America to the Court of St. James's; Sir Ludovic James Grant, Bart, Regius professor of public law in the University of Edinburgh; Mr. John Henry Muirhead, professor of philosophy in the University of Birmingham; Dr. William Stirling, Brackenbury professor of physiology in Victoria University in Manchester; and Sir William Taylor, K.C.B., Director-General of the Army Medical Service. With the conferring of the honorary degrees the interesting meeting terminated. Another interesting ceremony took place in the afternoon when there was presented to the University a memorial of the late Professor John Young, M.D., professor of natural history and keeper of the Hunterian Museum from 1866 to 1902. The memorial consisted of a medallion bearing in bas-relief a bust of the late professor. Mrs. Young and Queen Margaret College, in which Professor Young took a great interest, were presented with replicas of the medallion. In the evening a banquet was held at which over 200 gentlemen were present, including Principal Story, who presided, Sir William Ramsay, the Hon. the Lord Provost (Sir John Ure Primrose), the Hon. Joseph Choate, the Duke of Marlborough, the Earl of Stair, Sir Henry Craik, and Sir Ludovic Grant.—The medical classes in connexion with the University of Glasgow, Anderson's College Medical School, and St. Mungo's College opened on April 20th.

The Erection of the Deer Hospital: Interdict Craved.

Counsel were heard before Lord Pearson on April 16th in the Bill Chamber on an application for interdict at the instance of the trustees of Mr. George Alexander Baird of Strichen against the county council of Aberdeen and the Deer district committee of the council. The complainers sought to have the respondents interdicted from proceeding with the erection of an infectious diseases hospital on the estate of Strichen. They alleged that although negotiations for a site had taken place between the parties no concluded contract had been arrived at and that, as a matter of fact, a serious difficulty arose in connexion with the adjustment of a feu charter. Notwithstanding this they alleged that the respondents had commenced building operations and had refused to stop work pending the adjustment of the deed. The main question between the parties had reference to the adjustment of water rights between one of the complainers and the hospital. The respondents, who were heard upon a *caveat* against interim interdict, maintained that a contract of feu had been validly concluded and, therefore, had been followed by *rei interventus*, and in the circumstances they maintained that they were within their legal rights in proceeding with the works and they offered to meet with the complainers' agents and to adjust a clause in the charter to satisfy both parties. Lord Pearson said that he could not help regretting that matters here had come to be so acute. He would order answers in eight days and reserve as to interim interdict till the answers were advised. But he did entreat the parties—though he seldom said anything of the kind—to utilise the time even before answers were lodged, in the first place, to clear up their legal position, and, in the second place, to see if they could not find a *modus vivendi*, it might be as to the works being carried on under reservation but without the chance of the whole thing having to be undone, as it certainly would have to be if it proved in the end that there had been no concluded bargain.

April 26th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Sanitary Association.

AT the last meeting of the council of the Dublin Sanitary Association held on April 21st the following motion was passed unanimously:—

> That the attention of the Local Government Board be drawn to the unsatisfactory manner in which the Infectious Disease Notification Act, 1889, is still being worked in the Dublin metropolitan district. For example, chicken pox is notifiable in all the townships but not in the city; whooping-cough (at present epidemic and very destructive to child life) is notifiable in Pembroke but in none of the other districts

nor in the city; and measles is not notifiable in some of the districts, whereas it is scheduled as notifiable in others. The effect of this uncertainty in practice is to throw a serious obstacle in the way of notification.

Irish Dispensary Medical Officers.

The annual report of the Local Government Board of Ireland, which has just been presented to Parliament, contains a full and important statement in reference to the dissatisfaction of the Poor-law medical officers which, it is admitted, has existed for years. The Board draws attention to the gradual increase in the cost of the medical service which seems proved by statistics to have continued ever since the medical dispensary districts were established under the Poor Relief (Ireland) Act, 1851. The following appears in tabular form:—

Decades.	Total number of new cases.	Salaries paid.
1853 to 1862	7,542 429	£618 838
1863 to 1872	7,935,133	£740,290
1873 to 1882	6,699,791	£874,409
1883 to 1892	5,856 355	£899,792
1893 to 1902	5,966,579	£949,880

Those figures, it is stated, show a decrease of 20 per cent. in the number of the medical relief cases attended during the decade 1893–1902; and, on the other hand, an increase in the remuneration paid for medical services of 53 per cent. Those who are responsible for the report say that the enormous diminution in the population of Ireland from 6,552,055 in 1851 to 4,458,725 in 1901 and the consequent falling off in the amount of work done by the dispensary medical officers tend to support the opinion which has been formed. But in many unions a reduction of the staff of medical officers is not only feasible but is called for by the altered local circumstances. It is not stated that the decrease in the population, as recently reported by the Registrar General, was peculiar in the fact that it was the strong, well-to-do people of less than 35 years of age who have emigrated, leaving behind the poor, the old, the feeble-minded, and the chronic invalid. It would seem to me, therefore, that a fallacy may underlie the statement as regards "new cases" in the above statistical table, which apparently assumes that the practitioner's work is accurately measured by the number of "new cases" which he sees. As regards the question of holidays to medical officers the report goes on to say that the latter difficulty has in a great measure been overcome by the Local Government Act of 1898 providing for the recoupment out of the local taxation (Ireland) account of one-half of the remuneration paid by boards of guardians to the locum-tenent. The medical officer will not, however, forget that the Local Government Act of 1898 gave him a vacation of one month in the year during which his substitute would be suitably paid. Owing to some legal defect the Act has proved inoperative and even now the guardians can change the four weeks' leave to two weeks, or, on the other hand, refuse to pay the sum of four guineas per week to a substitute, so that the unfortunate practitioner cannot obtain a substitute and loses his vacation altogether.

The Public Health Committee of the Corporation of Dublin.

The public health committee of the corporation has just completed the by-laws under the provision of the Employment of Children Act, 1903. They deal with the regulation of street trading by children in the city of Dublin.

Ulster Medical Society.

The ninth general meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on April 21st, Dr. John Campbell, the President, being in the chair. Dr. V. G. L Fielden read a short paper on Ethyl Chloride as a General Anæsthetic. Mr. A. Fullerton showed the Stomach from a case of Ruptured Ulcer in an Hour-glass Stomach treated by suture and gastro-gastrostomy. Dr. Cecil E. Shaw showed Microscopic Preparations from some Cases of Catarrhal Conjunctivitis. Dr. W. L. Storey read a paper entitled "Undergraduate Days: Random and (rather) Personal Reminiscences of Class-room and Ward."

County of Cork Joint Hospital District.

The Local Government Board for Ireland has announced that the 28 sanitary districts in the county of Cork will be formed into a united district for the purpose of the provision, maintenance, and management of a hospital to be used as a sanatorium for consumptives for the benefit of the inhabitants of the sanitary districts in question. The joint board, which will be the governing body of the said united district, will consist of 56 representatives elected by the sanitary authorities of the district. Of these 56 representatives the county borough of Cork has seven, Cork rural district has seven, and Fermoy and Mallow rural districts have four each.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Graphic Method.

AT a recent meeting of the Academy of Sciences M. Lannelongue read a paper in which he explained that he described by the above name a method which had for its aim the giving both to the eyes and the understanding the power of appreciating with great exactitude the modifications in form and the change in relation of the various parts of the human body. Moreover, it was a method of portraying on the living body deformities, displacements, fractures, dislocations, increase or decrease in volume, differences of level, and the like, or shortly any alteration, both superficial and visible or deep-seated and invisible. The principle of the method lies in the comparison of the normal side of the body with that which is really or apparently deformed. The observer marks upon the two portions of the body which it is wished to compare the salient or re-entering portions, the contours and the relations, both deep and superficial, of the organs. Palpation and touch serve to mark them out. The method is not new in the sense that touch has never been previously employed to mark out individual regions of the body, but it has not hitherto been generalised or applied systematically. Its application to disturbances of the locomotive apparatus is new and very useful and is a helpful adjunct to radiography. It has been found specially serviceable in affections of the region of the hip, the elbow, the knee, the head the spine, and the instep. On the abdomen it is easy to mark out a pentagon which will show the situation of the organs. The method is applicable by all, even by the relatives of the patient. It is capable of at once offering a key to the diagnosis and of making it both easy and accurate. It is a lesson by facts which inscribe on the living body in their own place and without possibility of error the particularities of any region of the body so that their analysis is rendered easy.

The Pathological Agent of Human Trypanosomiasis.

At the same meeting of the Academy of Sciences M. Laveran recalled the fact that he had given the name trypanosoma Gambiense to a trypanosoma discovered by Ford and Dutton in the blood of a European who was suffering from irregular fever. This organism was first described by Dutton and later was found in a certain number of Europeans and in natives of the Gambia and Congo countries. Castellani still later notified that he had found in the cerebro-spinal fluid of certain negroes from Uganda who were suffering from sleeping sickness a trypanosoma which he described as of a totally distinct species and to which he gave the name of trypanosoma Ugandense. There seemed, however, to be some doubt as to whether these two organisms really were of different species and M. Laveran was given the opportunity of undertaking a research in order to set the question at rest. His researches led him to the conclusion that the two organisms were identical in species. Morphologically there was no difference between them, their pathogenic action on animals was identical, and an animal rendered immune against the trypanosoma Gambiense was also immune for the Ugandense variety and *vice versâ*. It has been fully proved that this trypanosoma is the cause of sleeping sickness but it must be remembered that it is often found in the blood of patients who die without ever having exhibited any symptom of sleeping sickness. M. Laveran is of opinion that the use of the name "sleeping sickness" should be abandoned. The term to use is "human trypanosomiasis," for this is applicable to all forms of the disease.

The Rouen Congress of Gynæcology, Obstetrics, and Pædiatrics.

The opening of the fourth session of the above national Congress took place recently at Rouen. The Mayor of Rouen was the president and there were also present the following nor in the city; and measles is not notifiable in some of the districts, whereas it is scheduled as notifiable in others. The effect of this uncertainty in practice is to throw a serious obstacle in the way of notification.

Irish Dispensary Medical Officers.

The annual report of the Local Government Board of Ireland, which has just been presented to Parliament, contains a full and important statement in reference to the dissatisfaction of the Poor-law medical officers which, it is admitted, has existed for years. The Board draws attention to the gradual increase in the cost of the medical service which seems proved by statistics to have continued ever since the medical dispensary districts were established under the Poor Relief (Ireland) Act, 1851. The following appears in tabular form :—

Decades.	Total number of new cases.	Salaries paid.
1853 to 1862	7,542 429	£618,838
1863 to 1872	7,935,133	£740,290
1873 to 1882	6 699,791	£874.409
1883 to 1892	5,856 355	£899,792
1893 to 1902	5,966,579	£949,880

Those figures, it is stated, show a decrease of 20 per cent. in the number of the medical relief cases attended during the decade 1893–1902; and, on the other hand, an increase in the remuneration paid for medical services of 53 per cent. Those who are responsible for the report say that the enormous diminution in the population of Ireland from 6,552,055 in 1851 to 4,458,725 in 1901 and the consequent falling off in the amount of work done by the dispensary medical officers tend to support the opinion which has been formed. But in many unions a reduction of the staff of medical officers is not only feasible but is called for by the altered local circumstances. It is not stated that the decrease in the population, as recently reported by the Registrar General, was peculiar in the fact that it was the strong, well-to-do people of less than 35 years of age who have emigrated, leaving behind the poor, the old, the feeble-minded, and the chronic invalid. It would seem to me, therefore, that a fallacy may underlie the statement as regards "new cases" in the above statistical table, which apparently assumes that the practitioner's work is accurately measured by the number of "new cases" which he sees. As regards the question of holidays to medical officers the report goes on to say that the latter difficulty has in a great measure been overcome by the Local Government Act of 1898 providing for the recoupment out of the local taxation (Ireland) account of one-half of the remuneration paid by boards of guardians to the locum-tenent. The medical officer will not, however, forget that the Local Government Act of 1898 gave him a vacation of one month in the year during which his substitute would be suitably paid. Owing to some legal defect the Act has proved inoperative and even now the guardians can change the four weeks' leave to two weeks, or, on the other hand, refuse to pay the sum of four guineas per week to a substitute, so that the unfortunate practitioner cannot obtain a substitute and loses his vacation altogether.

The Public Health Committee of the Corporation of Dublin.

The public health committee of the corporation has just completed the by-laws under the provision of the Employment of Children Act, 1903. They deal with the regulation of street trading by children in the city of Dublin.

Ulster Medical Society.

The ninth general meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on April 21st, Dr. John Campbell, the President, being in the chair. Dr. V. G. L. Fielden read a short paper on Ethyl Chloride as a General Anæsthetic. Mr. A. Fullerton showed the Stomach from a case of Ruptured Ulcer in an Hour-glass Stomach treated by suture and gastro-gastrostomy. Dr. Cecil E. Shaw showed Microscopic Preparations from some Cases of Catarrhal Conjunctivitis. Dr. W. L. Storey read a paper entitled "Undergraduate Days: Random and (rather) Personal Reminiscences of Class-room and Ward."

County of Cork Joint Hospital District.

The Local Government Board for Ireland has announced that the 28 sanitary districts in the county of Cork will be formed into a united district for the purpose of the provision, maintenance, and management of a hospital to be used as a sanatorium for consumptives for the benefit of the inhabitants of the sanitary districts in question. The joint board, which will be the governing body of the said united district, will consist of 56 representatives elected by the sanitary authorities of the district. Of these 56 representatives the county borough of Cork has seven, Cork rural district has seven, and Fermoy and Mallow rural districts have four each.

April 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Graphic Method.

AT a recent meeting of the Academy of Sciences M. Lannelongue read a paper in which he explained that he described by the above name a method which had for its aim the giving both to the eyes and the understanding the power of appreciating with great exactitude the modifications in form and the change in relation of the various parts of the human body. Moreover, it was a method of portraying on the living body deformities, displacements, fractures, dislocations, increase or decrease in volume, differences of level, and the like, or shortly any alteration, both superficial and visible or deep-seated and invisible. The principle of the method lies in the comparison of the normal side of the body with that which is really or apparently deformed. The observer marks upon the two portions of the body which it is wished to compare the salient or re-entering portions, the contours and the relations, both deep and superficial, of the organs. Palpation and touch serve to mark them out. The method is not new in the sense that touch has never been previously employed to mark out individual regions of the body, but it has not hitherto been generalised or applied systematically. Its application to disturbances of the locomotive apparatus is new and very useful and is a helpful adjunct to radiography. It has been found specially serviceable in affections of the region of the hip, the elbow, the knee, the head, the spine, and the instep. On the abdomen it is easy to mark out a pentagon which will show the situation of the organs. The method is applicable by all, even by the relatives of the patient. It is capable of at once offering a key to the diagnosis and of making it both easy and accurate. It is a lesson by facts which inscribe on the living body in their own place and without possibility of error the particularities of any region of the body so that their analysis is rendered easy.

The Pathological Agent of Human Trypanosomiasis.

At the same meeting of the Academy of Sciences M. Laveran recalled the fact that he had given the name trypanosoma Gambiense to a trypanosoma discovered by Ford and Dutton in the blood of a European who was suffering from irregular fever. This organism was first described by Dutton and later was found in a certain number of Europeans and in natives of the Gambia and Congo countries. Castellani still later notified that he had found in the cerebro-spinal fluid of certain negroes from Uganda who were suffering from sleeping sickness a trypanosoma which he described as of a totally distinct species and to which he gave the name of trypanosoma Ugandense. There seemed, however, to be some doubt as to whether these two organisms really were of different species and M. Laveran was given the opportunity of undertaking a research in order to set the question at rest. His researches led him to the conclusion that the two organisms were identical in species. Morphologically there was no difference between them, their pathogenic action on animals was identical, and an animal rendered immune against the trypanosoma Gambiense was also immune for the Ugandense variety and *vice versâ.* It has been fully proved that this trypanosoma is the cause of sleeping sickness but it must be remembered that it is often found in the blood of patients who die without ever having exhibited any symptom of sleeping sickness. M. Laveran is of opinion that the use of the name "sleeping sickness" should be abandoned. The term to use is "human trypanosomiasis," for this is applicable to all forms of the disease.

The Rouen Congress of Gynæcology, Obstetrics, and Pædiatrics.

The opening of the fourth session of the above national Congress took place recently at Rouen. The Mayor of Rouen was the president and there were also present the following primer is in use which is a move in the right direction, but in the mosque schools, which are not under the direct control of the Government, no such teaching exists and the cases of trachoma are found to vary from 80 to 90 per cent. The Egyptian can be taught anything by Englishmen and I venture to think that the time has come for him to learn that ophthalmia is preventable and in time he will learn to adopt the necessary measures for its prevention.

Cairo, April 17th.

Obituary.

FRANCIS JOSEPH LANDER, M.R.C.S. ENG., L.R.C.P. LOND.

CLOSE to his house in Stamford Mr. Lander met with a fatal accident on the afternoon of April 12th when out bicycling with his wife. Descending a rather steep lane which opened into a main road he lost control of his bicycle and dashed into a passing dray-horse. The base of his skull was fractured and he received other injuries. He was taken home and lingered until shortly after midnight when he died. Mr. Lander was a member of an old Leicestershire family. He received his medical education at the London Hospital and commenced his professional career as house surgeon to the Nottingham General Dispensary. He subsequently bought a practice in Nottingham, remaining there for about ten years, and was medical officer to the No. 1 Poor-law district. About a year ago, after a severe attack of pleurisy the state of his health gave rise to grave anxiety and he was strongly advised to leave Nottingham. This he did and after travelling for some time took a practice in Stamford four months ago. Here, completely recovered in health and in what he considered ideal surroundings, he looked forward to spending many happy years, but it was not to be. Mr. Lander was of a singularly gentle and loving disposition; he was not a pushing man and his interests were mostly centred in his profession. He had a sound knowledge of his work and succeeded in obtaining not only the confidence but also the esteem of his patients. He was 39 years of age. A widow and one young son lose a devoted husband and father.

JAMES FRANCIS TAPLIN, M.D., C.M. GLASG.

WE have to record the death of Dr. Taplin, the oldest medical practitioner in Small Heath, Birmingham, which took place suddenly at his residence in Coventry-road on April 14th. Dr. Taplin, who was 66 years of age, was born in Devonshire, his father being the Rev. James Taplin, a well-known Unitarian minister. When 16 years of age he was apprenticed for a term of six years to a firm of surgeons (Messrs. Pearse and Northey) at Tavistock and in 1860 he sailed in the *Windward* of Peterhead on a whaling expedition to the Arctic regions, in order to earn the requisite fees for completing his medical education. On his return he resumed his studies at Glasgow, acting for a time as dresser to Mr. (now Lord) Lister and finally graduated at that University, taking his M.D. in 1863 and C.M. in 1865. After obtaining his qualifications he went several voyages as a ship's surgeon to India, sailing *viâ* the Cape as the Suez Canal route was not then opened, and then settled down as assistant to a surgeon at Shaftesbury in Dorsetshire. His exceptional abilities and industry were at once recognised and he received an offer of partnership but his love of travel and adventure was not yet satiated and he accepted in preference an appointment on a tea plantation in Assam. Here he practised for a few years and before returning to England in 1872 he also practised for a short time in Calcutta where he was a member of a local lodge of Freemasons. Since he returned to England he has been engaged in general practice in Coventry-road, Small Heath, and his sudden death has come as a sad blow to his numerous friends and patients. Possessed of a genial and cheery manner and indefatigable energy he was greatly loved by all; whilst his wide experience and sound professional knowledge gained him a high reputation as a practitioner of medicine. Upright and conscientious in the highest degree he was a man of broad human sympathies, ever at the call of the sick and suffering, whether rich or poor.

For the last 32 years he devoted himself entirely to his practice and denied himself even much-needed rest and recreation in order to gratify the exacting demands of his oldest patients, many of whom owed their lives over and over again to his tireless devotion and attention. Until the very day of his death he had been in active work and his sad end has cast a gloom over the whole neighbourhood. If ever man was loved it was he, and now that he has laid down his arms his friends will treasure recollections of him as a kindly, honourable, and God-fearing gentleman. His son Mr. Julian Taplin has the sympathy of the profession in the irreparable loss which he has sustained.

GEORGE COCHÊT CHESNAYE, M.R.C.P., F.R.C.S. IREL., SURGEON-COLONEL, I.M.S.

Surgeon Colonel Chesnaye, whose death at his residence at Bournemouth on April 12th we announced in the Services column of THE LANCET of April 23rd, was born in 1838 and was educated in Dublin. In 1859 he received a commission in the Bengal Medical Service as assistant surgeon and was attached to the 3rd Bengal European Light Cavalry and two troops of Bengal Horse Artillery. At Mean Meer and at Amritsar during the cholera epidemic of 1861 he did some excellent work and received high praise from the Duke of Cambridge and from the Commander-in-Chief in India. He was in medical charge of the Lawrence Military Asylum at Sanawar from 1866 to 1868, Assistant-Field-Surgeon with the Hazara Field Force in 1868, and officiating residency surgeon at Khatmandu from 1869 to 1871, in which latter year he was appointed surgeon. He was in medical charge of the 4th Gurkha Rifles from 1871 to 1887 when he was appointed examiner of medical and fund accounts in Calcutta, having previously in 1873 reached the rank of surgeon-major. In 1889 he was promoted to deputy surgeon general, ranking as surgeon-colonel, and was appointed to the Lahore district, which post he held till 1894, when he retired. During the Afghan War of 1878–80 he took part in the capture of Ali Musjid, the expedition to Sherpore in December, 1879, the action of Zahidabad, the operations in Kohistan, the march from Kabul to Kandahar, and the battle of Sept. 1st. For his services in the Afghan War and in the Looshai Expedition of 1871–72 he was mentioned in despatches and received the thanks of the Government of India. In 1894 he was awarded a pension for distinguished and meritorious service. It is interesting to note that Surgeon Colonel Chesnaye's father, Captain J. C. Chesnaye, R.N., was a midshipman on board the *Orion* at Trafalgar.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Adolf Wertheimber of Munich, a voluminous writer on diseases of children, at the age of 72 years.—Dr. Stahr, surgeon-general of the Prussian army and until his retirement recently sub director of the Kaiser Wilhelms Academy in Berlin, at the age of 61 years.—Dr. Max von Strauch, *privat docent* of midwifery and gynæcology in the University of Moscow.—Dr. Lyot, surgeon to the Paris Hospitals.—Dr. V. I. Dobrovolsky, formerly professor of ophthalmology in the Military Medico-Chirurgical Academy of St. Petersburg.—Dr. Zarubin, formerly professor of clinical surgery in the University of Kharkoff.—Dr. V. Ratimoff, formerly professor of clinical surgery in the Military Medico-Chirurgical Academy of St. Petersburg.

MALARIA AND INFLUENZA IN RUSSIA.—The *Novosti* has a note from Voronesh as follows: "In our province malaria is increasing alarmingly and taking a very severe form. Round the town of Voronesh of late the epidemic has assumed such universal sway that scarcely a house or lodging has escaped. Thousands of otherwise healthy people are dying from it, whilst others remain very ill for months in spite of medical care. Its progress can be judged from the official figures as follows for 1901, 1902, and 1903—namely, 95,000, 130,000, and 160,000 cases respectively." The note adds that as the population can be with difficulty persuaded to call in medical aid and as the above figures are those of certified cases the totals may easily be called double those cited. Influenza, says the *Sviet*, is raging in Moscow in a special form, the malady being accompanied by a serious disturbance of the motor nerves.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The following gentlemen passed the first examination of the Board at the quarterly meeting of the examiners in the subjects indicated :—

Chemistry.—Alexander Baxendale, Owens College, Manchester; Arthur Cecil Barker Biggs, University College Hospital; Herbert Vernon Bettley-Cooke, Arthur James Brown, Charles Clarke, and Roderick Ernest Clarke, London Hospital; Sidney Howard Browning, Guy's Hospital; John Peter Clarke, University College, Liverpool; Reginald Cock, Charing Cross Hospital; Francis John Craddock, St. Bartholomew's Hospital; Ernest Edgar Davies, University College, Bristol; Archibald Wallace Duncan and George Douglas Gordon Fergusson, St. Mary's Hospital; Howell Woodwell Gabe, Middlesex Hospital; Claude Percival Rivers Harvey, London Hospital; Herbert Wilks Heasman, Guy's Hospital; Harold Leslie Hughes, St. George's Hospital; Harold Garnett Janion, University College Hospital; Joseph Arthur Alexander Kernahan, St. Bartholomew's Hospital; Henry Goff Kilner, Middlesex Hospital; Charles Eric Lowe, Westminster Hospital; Guy Harvey Mead, St. Thomas's Hospital; Charles Anderson Meaden, Birkbeck Institute; Henry Rubert Mullins, Oxford University and Guy's Hospital; Albert Edgar Nicholls, University College, Cardiff; Thomas Francis O'Mahony, London Hospital; Richard Goodhart Oram, Guy's Hospital; Charles Edward Hewett Paley and William Norman Awdry Paley, Westminster Hospital; Richard Alfred Parsons, St. Mary's Hospital; Michael William Phipps, Queen's College, Cork, and London Hospital; Edward Spencer Pierrepont, Technical Institute, Wandsworth; Ernest Alfred Pywell, St. Thomas's Hospital; Richard Bancroft Nevil Reade, St. Mary's Hospital; Martin Remers and James Rowland Rigg, Owens College, Manchester; Frank Rendall, London Hospital; Arthur Rhodes, Birkbeck Institute; Reginald George Riches, St. Bartholomew's Hospital; William Sidney Simpson and Philip Edward Stibbe, Charing Cross Hospital; Charles Raymond Start, Felsted Schools; Donald Wainwright, Middlesex Hospital; William Hall Watson and Francis James Wheeler, Guy's Hospital; Cyril Howard Welch, King's College Hospital; Howel Meirig Williams, University College, Aberyswyth; and Henry Adrian Fitzroy Wilson, St. Thomas's Hospital.

Practical Pharmacy.—John Avery and Norman Huthnance Bye, London Hospital; Frederick Charles John Baker, King's College and St. Mary's Hospitals; Ernest James Chambers, Westminster Hospital; Richard Julius Cyriax, Edinburgh University; John William Dadd and Alfred William Eyles, Guy's Hospital; Edward Peter Joseph Dawes, Birmingham University; Lionel Cecil Ferguson, St. Bartholomew's Hospital; George Finch, Yorkshire College, Leeds, and St. Thomas's Hospital; William Henry Flint, Birmingham University; Bertram Maughan Footner, King's College Hospital; Reginald Franklin and Raymond Sydney Harper, Guy's Hospital; Leonard Austen Harwood, private study; Stanley Heathcote, Owens College, Manchester; Arthur Tease Jackson, L.D.S. Eng., University College, Sheffield; Henry Hollis Jenkins, Guy's Hospital; Thomas Lloyd Kenion, University College, Liverpool; Henry Andrew Lash, St. Mary's Hospital; John Daniel Stuart Lloyd, Birmingham University; Alfred Cecil Martin, London Hospital; Charles Anderson Meaden, private study; Leonard Myer, L.D.S. Eng., Guy's Hospital; Harry Williams Nicholls, Middlesex Hospital; Oswald Sinclair Norton, Guy's and Westminster Hospitals; Charles William O'Brien and Arthur O'Neill, St. Bartholomew's Hospital; William Stewart Orton, Guy's Hospital; Edward Symes Prior, University College, Bristol and Middlesex Hospital; Robert Montgomery Rendall, David Harold Richards, Gerald Charles Frederick Robinson, and Henry Warr Bennett Walling, Guy's Hospital; Charles Raymond Start, private study; Henry James Davey Walker, London Hospital; John Warburton, Owens College, Manchester; and Sydney Williams, University College, Cardiff.

Elementary Biology.—Stanley Denovan Adam, Rupert Blake Adams, and Frank Basford, St. Mary's Hospital; Edward Bruce Allnutt, John James Harkness Beckton, and Norman Barnett Benjafield, St. Bartholomew's Hospital; Alexander Baxendale and George Noel Braham, Owens College, Manchester; Hubert Vernon Bettley-Cooke, London Hospital; Sidney Howard Browning, Guy's Hospital; Cuthbert John Butler, Charing Cross Hospital; Charles Adolph Caufman, St. Thomas's Hospital; Ernest James Chambers, Westminster Hospital; John Peter Clarke, University College, Liverpool; Roderick Ernest Clarke, London Hospital; Reginald Charles Clifford, St. Bartholomew's Hospital; Reginald Cock, Charing Cross Hospital; Benjamin Dale, St. George's Hospital; David Davies, London Hospital; Sidney Alfred Day, St. Mary's Hospital; John William Doherty, Birkbeck Institute; Charles Stuart Douglas and Arthur Downes, St. Bartholomew's Hospital; John Griffiths Edwards, City of London College; Bernard Grainger Goodwin, University of Birmingham; Richard Sydney Graham, St. Mary's Hospital; Gilbert Clement Gray and Percy Hall, St. Bartholomew's Hospital; Eric John Durnford Haining, University College, Bristol; Martin Hallam, University College, Sheffield; Philip Thomas Harper, St. Thomas's Hospital; William Gladstone Harrop, Owens College, Manchester; Claude Percival Rivers Harvey, London Hospital; Leonard Austin Harwood, Birkbeck Institute; William Henry Stewart Hodge, St. Bartholomew's Hospital; Gilbert Percy Humphry, St. George's Hospital; Harold Garnett Janion, University College Hospital; Thomas William Jones, Charing Cross Hospital; Charles Eric Lowe, Westminster Hospital; Russell Hardy Sidney Marshall, St. Mary's Hospital; Francis Leslie Nash-Wortham and Tha Htoon Oo, St. Bartholomew's Hospital; Albert Edgar Nicholls, University College, Cardiff; Thomas Francis O'Mahony, London Hospital; Thomas Godfrey Percival and Clifford Crawshaw Pickles, Yorkshire College, Leeds; Archibald Bruce Pettigrew, University College, Sheffield; Michael William Phipps, London Hospital William Howard Pickup, Birmingham University; Cyril Macdonald Plumptree and Humphry Cooper Pugh, Guy's Hospital; Edward John Joseph Quirk, Charing Cross Hospital; George Frederick Randall, Middlesex Hospital; Martin Remers, Owens College, Manchester; Arthur Rhodes, Birkbeck Institute; James Freer Richardson, London Hospital; Arthur Bodley Scott, St. Bartholomew's Hospital; William Sidney Simpson, Charing Cross Hospital; Herman Spitz, St. Bartholomew's Hospital; John Startin, St. Thomas's Hospital; Phillip Edward Stibbe, Charing Cross Hospital; John Edgar Taylor, Yor[illegible]. Henry Hercules Skinner Templeton, [illegible]ol; Carl Rudolf Baltzar von Braun and C[illegible] St. Bartholomew's Hospital; Arthur Henry Leopo[illegible], Harold Eustace Wall, Jocelyn Langton Waller, and John Beazley Webb, St. Mary's Hospital; David Phillips Williams, Charing Cross Hospital; Sydney Williams, University College, Cardiff; Henry Adrian Fitzroy Wilson, St. Thomas's Hospital; and Pelham Vansittart Wynn-Wernnick, Merchant Venturers' Technical College, Bristol.

SOCIETY OF APOTHECARIES OF LONDON.—At the examination held in April the following candidates passed in the subjects indicated :—

Surgery.—G. Dewick (Sections I. and II.), St. Thomas's Hospital; W. S. Gibson (Sections I. and II.), Manchester and Charing Cross Hospital; C. Kellgren (Section I.), Royal Free Hospital; L. H. Lewis, Middlesex Hospital; H. J. May (Sections I. and II.), London Hospital; F. H. Hand (Section II.), St. Mary's Hospital; A. B. S. Todd (Sections I. and II.), Leeds; and T. R. Waltenberg (Section II.), Manchester.

Medicine.—A. Anderson (Sections I. and II.), Leeds; G. J. Eady (Section I.), St. Bartholomew's Hospital; J. H. Harrison (Section I.), Sheffield; J. A. Kilpatrick (Section II.), King's College Hospital; C. S. Scott (Section I.), St. Bartholomew's Hospital; and R. W. L. Wood (Sections I. and II.), Leeds.

Forensic Medicine.—M. O. Dollie, University College Hospital; G. J. Eady, St. Bartholomew's Hospital; H. R. Grellet, Guy's Hospital; H. G. Peel, Leeds; L. S. Veale, Royal Free Hospital; F. J. Waldmeier, London Hospital; and R. W. L. Wood, Leeds.

Midwifery.—A. Anderson, Leeds; H. H. R. Bayley, Charing cross Hospital; A. G. C. Findlay, University College Hospital; W. A. T. Lloyd, London Hospital; W. S. Mitchell and E. D. Richardson, St. Mary's Hospital; A. B. S. Todd, Leeds; L. S. Veale, Royal Free Hospital; J. S. Ward, Sheffield; and J. A. R. Wells, St. Thomas's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: G. Dewick, F. H. Hand, L. H. Lewis, H. G. Peel, and F. J. Waldmeier.

UNIVERSITY OF CAMBRIDGE.—The following have been appointed members of the State Medicine Syndicate which will conduct the examination for the diploma in Tropical Medicine and Hygiene: Mr. H. E. Durham, Dr. J. W. W. Stephens, and Dr. F. H. H. Guillemard.—Mr. D'Arcy Power has been appointed an additional examiner in surgery and Dr. J. R. Bradford an additional examiner in medicine for the M.B. degree.—The first, second, and third (Part I.) examinations for M.B. will begin on June 13th. Names have to be sent to the tutors of Colleges by May 26th.—The following candidates have satisfied the examiners in both parts of the sanitary science examination for the Diploma in Public Health :—

Edward Baines, Gonville and Caius; Wilfred William Ogilvy Beveridge, Basanta Kumar Chatterjee, Thomas Aldous Clinch, Myer Coplans, Ernest King Gawn, Edward Samuel Gorman, Arthur Edward Horsfall, Henry Louis Powell Hulbert, Trinity; Arthur Charles Ingram, St. John's; James Conway Jameson, Ramsay Millar, Thomas Rhind, and Eliot Swainston.

UNIVERSITY OF DURHAM.—At examinations for the degree of Bachelor in Medicine held recently the following candidates satisfied the examiners :—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry and Physics.—*First-class Honours:* Frank Rawlinson Dudderidge, College of Medicine, Newcastle-upon-Tyne. *Second-class Honours:* Charlotte Purnell, London School of Medicine for Women. *Pass List:* Frederick William Cheese, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Helen Mary Gurney, Gertrude Ethel O'Brien, Hubert Shield, and Joseph Albert Sacco, College of Medicine, Newcastle-upon-Tyne; Herbert James Slade, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; and Charles Sim Thompson, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—Kenneth Bruce Allan, College of Medicine, Newcastle-upon-Tyne; Harold Ernst Bloxsome, St. Bartholomew's Hospital; Leonar[illegible] Browne, College of Medicine, [illegible]ospital; Newcastle-upon-Tyne; Lione[illegible] [illegible]llege of Elizabeth Niel Havelock and [illegible] King, Medicine, Newcastle-upon-T[illegible] School St. Bartholomew's Hospital; [illegible] Robert of Medicine for Women; Francis Aidan [illegible] Henry Smallwood, M.A., and Basil Taylor, College of Medicine, Newcastle-upon-Tyne; and John Franklin Young, Guy's Hospital.

Chemistry and Physics.—Hubert Cyril Willoughby Allott, Guy's Hospital; Herbert Ridley Crisp, William Harold Edgar, and Frank Widowfield Melvin, College of Medicine, Newcastle-upon-Tyne; Theresa de Gournay Miller, London School of Medicine for Women; and Frank Walter White, College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—*Second-class Honours.*—David Ranken, College of Medicine, Newcastle-upon-Tyne.—*Pass*

THIRD EXAMINATION.

First class Honours.—James Glenny Gibb, St. Bartholomew's Hos-

and James Leslie Wilson, M P., College of Medicine, Newcastle-upon Tyne.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF ıe Conjoint Board helc passed the respective :—

First Examination.—Owen Thomas Jones, Bangor, North Wales (with distinction), and Fred. Garnet Allan, Whaley Bridge,

Rigby, Pontefract.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—At the second professional examination held recently candidates have passed as undernoted :—

Honours, in order of merit.—George Sheppard, Thomas T. O'Farrell, and R. M. Bronté

Passed in all subjects—Miss H O. D Beamish, T. A. Buchanan, T. Crowley, H. J. Raverty, and R. O. Kelly.

Completed the examination.—P. M Carroll, J. Daniell, M. I. Kelly, B C. A. Leeper, I. H. Lyne, I. G McGreal, H. V. McKeogh, James O'Brien, W. B. Soady, and M. Walters.

In the list of honours at the first professional examination recently published Mr. A. E. S. Martin's name was inadvertently omitted.

FOREIGN UNIVERSITY INTELLIGENCE—*Bologna:* Dr. U. Gardini of Modena has been recognised as *privat docent* of Operative Medicine.—*Gottingen:* Dr. Paul Stolper, *privat-docent* of Forensic Medicine, has been promoted to an Extraordinary Professorship.—*Padua:* Dr. Luigi Lucatello, Extraordinary Professor of Internal Pathology, has been promoted to the Ordinary Professorship. Dr. Riccardo Avanzi has been recognised as *privat-docent* of Psychiatry.—*Pavia:* Dr. Innocente Olivio, Extraordinary Professor of Midwifery and Gynæcology, has been promoted to an Ordinary Professorship. Dr. M. Albanese has been appointed Professor of Materia Medica and Experimental Pharmacology.—*Prague (German University):* Dr. Ferdinand Schenk has been recognised as *privat docent* of Midwifery and Gynæcology; Dr. Oskar Bail, *privat-docent* of Hygiene, has been promoted to an Extraordinary Professorship.—*Rome:* Dr. Giuseppe Vannini has been recognised as *privat-docent* of Internal Pathology, and Dr. Ernesto Guarnaccio as *privat-docent* of Oto Rhino-Laryngology.—*St. Petersburg (Military Medico Chirurgical Academy):* Dr. Boris Sloutzoff has been recognised as *privat-docent* of Physiological Chemistry and Dr. Alexander Lasurski as *privat docent* of Neurology and Psychiatry.—*Strasburg:* Dr. Paul Ascher has been recognised as *privat-docent* of Children's Diseases.—*Tubingen:* Dr. Hugo Lüthje has been recognised as *privat-docent* of Internal Medicine and Dr. Bernhard Honsell as *privat docent* of Surgery.—*Vienna:* The chair of Dermatology, vacated by the retirement of Dr. Neumann, has been filled by the appointment of Dr. Ernst Finger. Dr. Siegmund von Schumacher has been recognised as *privat-docent* of Anatomy.

CALLS TO THE BAR.—Among those gentlemen called to the Bar on Wednesday, April 27th, we note the names of Mr. Digby Cotes-Preedy, M.A. Cantab., L S A. Lond, of the Inner Temple and late house physician at St. George's Hospital; Mr. E. F. Goodhart, B.A. Oxon., of the Inner Temple, son of Dr. J. F. Goodhart of London; and Mr. H. S. Maurice, B A. Oxon., of Lincoln's Inn, son of Dr. J. B. Maurice of Marlborough.

DONATIONS AND BEQUESTS.—The treasurer of the London Hospital has received from Mr. Edward Davis, of Cheltenham, a donation of £1000 and from the Clothworkers' Company a donation of £200, being the second instalment of the contribution of £1000 voted by its court. —The late Mr. William Sutton, M.D St. And., M.R C.S. Eng., has by his will bequeathed £1000 to the Dover Hospital and Dispensary and a like sum to the Royal Medical Benevolent College at Epsom and to the British Medical Benevolent Fund, £500 to St. Thomas's Hospital, £300 to the Institution of Trained Nurses at Dover, £250 to the London Hospital, and similar sums to Guy's Hospital, Charing Cross Hospital, and the Royal Free Hospital.

PLUMBERS' EXAMINATION AT KING'S COLLEGE.—23 plumbers applying for registration under the National Registration of Plumbers attended at King's College on April 23rd for examination by the Worshipful Company of Plumbers. The candidates were from various parts of London and also from Cambridge, Dorking, Egham, Esher, Hemel Hempstead, Sevenoaks, Walton-on-the-Naze, and Windsor. The practical test included lead bossing and the making of plumbers' joints, &c. The examination questions included the subjects of contamination of drinking water from faulty connexions, roof covering, arrangement of bath, sink, and closet wastes, drainage of town houses, and disconnexion with sewers. The examiners were: Mr. Joseph Johnson and Mr. Charles Thomerson, master plumbers; and Mr. W. Smeaton and Mr. F. Wyatt, representing the United Operative Plumbers Association of Great Britain and Ireland. Five candidates succeeded in passing the examination.

STATE REGISTRATION OF NURSES.—On April 22nd a meeting was held at the Chelsea Infirmary to discuss the question of State registration for nurses. Miss Isla Stewart, the matron of St. Bartholomew's Hospital, occupied the chair, and the speakers included Lady Helen Munro Ferguson, Mr. James Cantlie, Mr. Richard Rigg, M.P., Miss Mollett, matron of the South Hants General Hospital, and Mrs. Bedford Fenwick. Miss Stewart told the meeting that to her knowledge many of those women who had been dismissed from St. Bartholomew's Hospital as incompetent were now earning two guineas a week as private nurses. Mr. Cantlie argued that it was unfair to the general body of nurses that the metropolitan hospitals' certificates should acquire a value superior to that of equally well organised hospitals in the provinces and that if the training of nurses was properly organised in all hospitals under a central council it would be of advantage to the great body of nurses. He said that there were just as good surgeons and training schools in Birmingham, Edinburgh, or Glasgow as there were in London and the certificate of nurses trained in any such approved training school should be recognised as equal to those of their London trained sisters. Miss Mollett showed from her own experience how many nurses left the general hospitals totally unable to assist surgeons at operations because such work was undertaken by the students in the larger training schools. She instanced her own sense of incompetency on first leaving her training school and being asked to assist at a major operation. Mr. Rigg dwelt on the Parliamentary aspect of the question and advocated a select committee to inquire into the whole subject. He undertook to give all the assistance in his power. The following motion was put to the meeting and unanimously carried: "That this meeting warmly supports the principles of State registration for nurses."

FOOTBALL ACCIDENT. — A football fatality occurred at Weston-super-Mare on April 23rd, a young man fracturing his skull by colliding with another player.

PRESENTATION TO A MEDICAL PRACTITIONER.— Mr. Richard Julyan George, M.D., C.M. Edin., of Port Isaac, Cornwall, has been presented by the committee of management of the Royal National Lifeboat Institution with a Ross binocular glass in recognition of his valuable and generous efforts in behalf of the institution during the past 11 years whilst holding the office of honorary secretary to the Port Isaac branch.

SMALL-POX IN LONDON.—The report of the Public Health Committee presented to the London County Council shows that in the two days of the week ending April 9th, the first week in which chicken-pox was notified in London, 200 cases of this disease were certified and that in the subsequent week this number amounted to 704, while in the week ending April 23rd 574 cases were notified. The services of Mr. Samuel Bingham and Mr. W. McC. Wanklyn for the diagnosis of doubtful cases of small-pox in London had up to April 21st been utilised in 33 instances, 16 of these cases proving to be small-pox, seven to be chicken-pox, and the remaining 10 to be other diseases. The large experience which these gentlemen have had of small-pox whilst in the service of the Metropolitan Asylums Board will prove of especial value in the present prevalence.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The following prizes for the winter session 1903–04 have been awarded:—First year students: J. A. Clark, the William Tite scholarship, £25; R. W. Rix, College prize, £20. Second year students: H. J. Nightingale, the Peacock scholarship, £35; A C. F. Turner, College prize, £20; H. G. Bennett, College prize, £10. Fifth year students: A G. Gibson (medicine), £10; H. A. Kisch (surgery), £10; C. E Palmer (midwifery and diseases of women), £10; A G. Gibson (pathology), the Haddon prize, £10; K. Takaki (pharmacology and therapeutics) and F. A. Broadribb and E. W. Parry (forensic medicine and insanity) £5 each The Mead medal for proficiency in medicine, pathology, and hygiene was awarded to K. Takaki; the Wainwright prize £10, and the Seymour Graves Toller prize were awarded to A. G. Gibson, of Christ Church, Oxford; and the Cheselden medal for proficiency in surgery and surgical anatomy was awarded to H. A. Kisch.

AMBIDEXTRAL CULTURE SOCIETY.—A lecture on Ambidexterity and Primitive Man was delivered before the above society on April 20th by the Rev. H. Dukinfield Astley. Mr. Noble Smith was in the chair. The following is an abstract of the lecture. "Primitive man" here means early or prehistoric man. The analogy of the quadrumana, apes and monkeys, makes it probable that man in his beginnings was ambidextrous. The evidences that he was so are few but sufficient. These consist of:—1. Flint implements from the plateaux of Kent, near Ightham, which date from man's earliest appearance in Britain and have been called "eolithic," though I would prefer to call them "proto-palæolithic." At any rate they go back to the first inter-glacial period and are probably contemporary with the Tilloux-Taubach deposit in France. Among these, rude and rough though they are, scrapers, hammers, and pounders have been found clearly adapted for use in the left hand, and these as numerous as those adapted for use in the right 2. As time went on palæolithic man learnt to heft his implements and weapons, hence it is difficult to say anything definite as to these. But he was an artist—on the fact that his representations of the mammoth, the reindeer, horses' heads, &c., were drawn with equal facility from right
left as from left to right, we have evidence that

ambidexterity and the right hand was becoming more and more the active member in the economy of the body and the left hand the passive. This was due to the fact that in hunting and in warfare the right hand was used for offence, the left for defence. In spite of this the evidence of early Greek and Roman inscriptions, written in what is called the "boustrophedon" style—i.e., alternately from left to right and from right to left—goes to show that ambidexterity was still practised in writing. Babies are naturally ambidextrous and children, who commence conscious life at the neolithic stage of culture, are so also and would continue so were they not taught otherwise. It is said that "idiots" show a marked tendency to revert to this type and also "persons of genius."

THE MEDICAL GOLF TOURNAMENT.—The medical golf tournament for 1904 is to be held on Thursday, June 9th, at Northwood by the courtesy of the Northwood Golf Club. This annual fixture has become very popular and a successful meeting in point of numbers is already assured, so that if the competitors are favoured with a fine day the attendance will probably be a record one. It is fortunate that the Northwood golf links have been again secured for the tournament because the club is a well-known rendezvous for medical golfers, has the advantage of a frequent service of trains from Baker-street station, and the club-house is connected with the telephone. The details of the programme are as follows. In the morning 18 holes will be played, match play *v.* Bogey, and no match may start later than 3 P.M. Players will be divided into two classes: Class 1, handicaps of 12 and under; Class 2, handicaps of more than 12 (24 limit); and members of the Northwood Golf Club will have two deducted from their handicap. There will be a first and second prize and a prize for the best score for the last nine holes *v.* Bogey in each class. There will be a foursome sweepstake competition *v.* Bogey in the afternoon. Players are to arrange their own matches or they can apply to the honorary secretary of the tournament, stating the time that they wish to play. Entries, mentioning lowest handicap and inclosing a 5*s.* entry fee, should be made on or before June 8th, to the honorary secretary, Mr. Rolf Creasy, Windlesham, Surrey.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Nourishment of School Children.

IT had been hoped that the whole of the evening sitting on April 20th would be devoted to the discussion of Mr. CLAUDE HAY's motion in regard to the nourishment of school children but, unfortunately, at the last moment another matter obtained precedence and Mr. HAY was unable to speak before 11 o'clock. No division was possible in these circumstances. There was evidence, however, in the brief debate that arose that the matter was viewed with general sympathy. The motion put to the House read as follows:—"That the Board of Education should require arrangements to be made by the local education authorities whereby every child compelled by law to attend a public elementary school shall have received proper nourishment before being subjected to mental or physical instruction and that in cases in which proper food has not been provided for the child by its parents it should be first supplied by the local education authority and subsequently suitable action taken to recover the cost."

HOUSE OF COMMONS.

WEDNESDAY, APRIL 20TH.

Alleged Evasion of the Factory Acts.

Mr. FORDE RIDLEY asked the Home Secretary whether his attention had been called to a statement lately made by one of the sanitary inspectors of the borough of Bethnal Green as to the evasion of the Factory Acts in consequence of workrooms being part of tenement houses, thus avoiding inspection by the authorities as to the sanitary conditions, overcrowding, and other circumstances in which the work was done; and, if so, whether he could give any hope of these evils being remedied by the issuing of an Order in Council or other method.—Mr. AKERS-DOUGLAS replied: I do not clearly understand the question and I think there may be some misconception. So far as I can gather from inquiries, the statement referred to did not attribute any difficulty in enforcing the Factory Acts in workrooms to the fact that they form part of tenement houses, and, as a fact, the provisions of that Act are enforceable equally in tenement houses as elsewhere. I understand that it is a rule in Bethnal Green that these houses should be visited once a month. On the information before me no question appears to have arisen which calls for further action on my part.

Soldiers and Sailors in Lunatic Asylums.

Mr. JAMES O'CONNOR asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the number of British sailors

There is no Treasury contribution in aid of the maintenance of discharged sailors and soldiers while so confined, but the ordinary capitation grant is payable in such cases out of the local taxation account.

Candidates for Dental Appointments.

Mr. SHACKLETON asked the Secretary of State for War whether his attention had been called to the fact that the expenses of the candidates for dental ap

Nicholas Kelynack, to Clara [illegible] only daughter of the late [illegible] Mrs. Cooper, Ilston House, Ilston.

DEATHS.

MacDonald.—At 18, Castle-street, Dumfries, on April 19th, Alexander Dall MacDonald, M.D., &c., in his 59th year.

Palmer.—On April 23rd, at Newbury, Berks, Montagu Humphrey Courtenay Palmer, M.R.C.S., L.R.C.P., aged 32 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WHAT IS THE TRICK?

A medical man has sent to us the circular which follows. It is evidently a variant of the circular upon which we commented in The Lancet of April 13th, 1901, p. 1117. But the high aristocrat grows no older, for he was forty years of age in 1901. Our correspondent says "I fail to see how the advertiser is going to make it pay," and we are in the like situation, though we have a feeling that there is a swindle somewhere. Possibly some of our readers may have more *flair* for that swindle than we have. This is the circular:—

> "Dear Sir,
>
> "Philantropist of high aristocracy, 40 years old, millionaire, wishes for special motives to get married to a distinguished lady——"

A gap here follows which we presume is to be filled by the words upon a separate slip of paper which are—

> "*who is in the (interesting) situation of hopefulness.*"
>
> "Splendid pecuniary compensation is assured. Any intelligence-office in Vienna will give you informations about me.
>
> Yours respectfully, ——."

The circular is sent out in German, English, and French. Yet another slip of paper bears the name of the sender who claims to be a baron and a captain in the navy and gives as his address Lovrana. [illegible] also distinguished. That the story is rubbish is certain, but what we want to know is wherein does the swindle lie? If no money is to be made by the dissemination of the circulars, for what purpose are they distributed?

A NEW DISEASE.

The following paragraph which we reproduce from a contemporary will be of special interest to those concerned with tropical diseases.

> "TYMPANOSOMA."
>
> Colonel David Bruce, who lectured on "the sleeping sickness in Uganda," stated that on the examination of blood taken from a patient a little wormlike parasite was found.
>
> This was called a "tympanosoma," and was only found in sufferers from the disease.

TO MEDICAL FREEMASONS.

To the Editors of The Lancet.

Sirs,—May I through the medium of The Lancet thank those who sent me votes for the medical candidates in the recent elections for the Royal Masonic Educational Institutions for their response to the appeal which was published in your issue of March 19th? The boy, Patrick Trevor Webster, was successful with 4041 votes, being twenty-first out of the 30 candidates elected. The girl, Irene Mabel Sewart, was unfortunately not successful and only polled 398 votes. But we hope that a unanimous response from medical Freemasons at the October elections will insure her success. The election for the Royal Masonic Benevolent Institution for Aged Freemasons and the Widows of Freemasons will take place on Friday, May 20th. Mrs. Georgina Skinner, widow of the late W. Bro. David Skinner, M.D., late medical officer of health of Willesden (P.M. 665, 1974; P.Z. 890) is the candidate whose claims were advocated in a previous issue of The Lancet. May I once more appeal for votes on behalf of this most deserving case which will especially appeal to medical Freemasons. Votes will be thankfully received by myself or our treasurer, Dr. J. Eyre, Wandle House, Wandle-road, Upper Tooting, S.W.

I am, Sirs, yours faithfully,

Harold S. Sington,

Secretary, St. Luke's Medical Lodge of Instruction.

44, St. Mary's Mansions, W., April 23rd, 1904.

RED GLASSES IN THE TREATMENT OF BLEPHARITIS.

A correspondent who writes from Bangkok, Siam, states that he has long suffered from sore eyes and has been wearing dark glasses as a relief from the glare. On reading Finsen's experiments he became convinced that "although the dark glasses were a protection to the eye as the organ of vision they were causing the soreness of the eyelids." He therefore discarded the dark glasses and wore colourless ones and "in a single day the soreness of the eyelids disappeared." He proceeds to ask whether the use of red glasses for a short period might not be equally efficacious. Our correspondent does not say whether he has used lenses for the correction of his probable errors of refraction, nor does he give any particulars in regard to the amount or kind of his work or the conditions under which it is performed, so that no conclusions can be drawn from his particular case, but the suggestion that the wearing of close-fitting goggles with red glasses for a short period daily where the ordinary methods of treatment fail might be serviceable is perhaps worthy of consideration, the more so as it is of easy application.

SPITTING ON THE GROUND.

To the Editors of THE LANCET.

SIRS,—A recent contributor to your paper expressed regret that spitting on the ground was not a penal offence. But were it so, how does he think we who are subject to bronchial colds should meet the difficulty? My doctor tells me to walk about. He also forbids me to swallow what my cough brings up. He would hardly suggest the handkerchief, recourse to it being often not feasible.

I am, Sirs, yours faithfully,
ANTI-SYBARITE.

⁂ Surely if spitting on the ground is feasible spitting into a handkerchief is equally so. But the handkerchief should be of paper, so that it may be burned without loss. Pocket spittoons are also made. —ED. L.

HOLMAN TESTIMONIAL FUND.

THE following further list of contributions has been forwarded to us by the honorary treasurer of this fund, Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., by whom or by the secretary, Mr. W. A. Berridge, Oakfield, Redhill, Surrey, subscriptions will be received:—

THE USE OF HOT BOTTLES AFTER SURGICAL OPERATIONS.

To the Editors of THE LANCET.

SIRS,—I read with interest and regret Mr. H. P. Symonds's letter on the above subject. I have worked in a good many hospitals and have been struck with the fact that few teach nurses the most essential things: too much is taken for granted; common sense is not largely developed in everyone. Sisters should take care that the nurses they are training do know the many little but important things that go to make a good nurse. Nowadays, nurses are taught so much theory that the practical work is apt to slip. I can never be thankful enough for the excellent training I received in one of the four large London hospitals, and in no hospital that I have worked since have I found a nurse who had received so much teaching in detail as I have; the great thing seems to be to "get through," no matter how. If sisters would only show nurses *how* to do things instead of telling them to do them there would not be so many regrettable accidents.

I am, Sirs, yours faithfully,
April 26th, 1904. A NURSE OF FOURTEEN YEARS' STANDING.

AN ORIENTAL FIBRE TOOTH BRUSH.

THE Oriental Fibre Tooth Brush Company has submitted to us a form of tooth brush which presents many advantages over those made with bristles. The material of the brush itself is a wood fibre, the wood being stated to come from a tree known as Al-Arak. The brush, which is detachable, is set into the handle by means of a clip ring so that it can easily be taken out and a new one substituted. From a personal trial we can say that it is a good cleanser and, moreover, the lingual surfaces of the teeth can be as easily cleansed as the buccal surfaces, an act which is almost impossible with the ordinary tooth brush. A quotation is given in an accompanying pamphlet from a paper by Dr. Harry Campbell which appeared in our columns on August 8th, 1903, regarding the merits of a tooth brush of similar material. The quotation is headed, "Extract from the London Lancet." This is true so far as it goes but it implies that the extract is from editorial matter which is not the case. This, however, does not detract from the value of the tooth brush, the manufacturers of which are the above-mentioned company, of Farnham, Surrey. The price of the holder is 1*s.* and a box containing 12 brush heads costs another 1*s.*

◆

Tight Corner (Africa).—The case as described by our correspondent is a most difficult, delicate, and embarrassing one which fully justifies the choice of his pseudonym. The details furnished are in the circumstances insufficient to enable us to offer an opinion. Only a complete knowledge of all the minutiæ of the case would justify us in recommending to our correspondent, who has our sympathy, the course of action which he should pursue. We trust that his own good judgment and sense of responsibility together with his acquaintance with the persons and the surroundings of the case will enable him to arrive at a wise conclusion. A consultation, if obtainable, with some other practitioner whose opinion would have weight with him, we think desirable.

K. A. N.—There are practically two institutions granting certificates of the kind mentioned by our correspondent. One is the Royal Institute of Public Health, 18, Bloomsbury-square, London, W.C., which grants certificates of "having passed an examination as sanitary inspector," and the other the Sanitary Institute, Margaret-street, Regent-street, London, W., which holds examinations and grants certificates of competency in sanitary knowledge. Examinations for inspectors of nuisances and for meat inspectors are also held.

Sceptic.—The regulations for admission to the examination for the diploma of F.R.C S. England vary according to the time at which the would-be candidate has commenced professional study. They will be found in Section 20 of the By-laws of the Royal College of Surgeons of England which are published in the Calendar of the College.

Medico.—Our correspondent must obey the subpœna but is at liberty to ask, before he is sworn, for payment of his fees which probably would be £1 1*s.* per diem and second-class railway expenses. As to question (2) that must be a matter of arrangement between our correspondent and his principal.

E. S. W.—We do not think that there is any objection to our correspondent putting up a plate with an intimation that he attends at the house in question on certain days of the week at certain hours.

H. V. (Paisley).—We see no objection to a practitioner stating on his door-plate the hours during which he will be found at home. The style is a matter of indifference but possibly "At Home" is the more usual.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M., St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by *them?* Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not onl affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies onl should be forwarded.

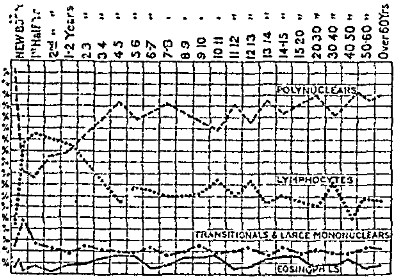
Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manage Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addresse

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adve tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

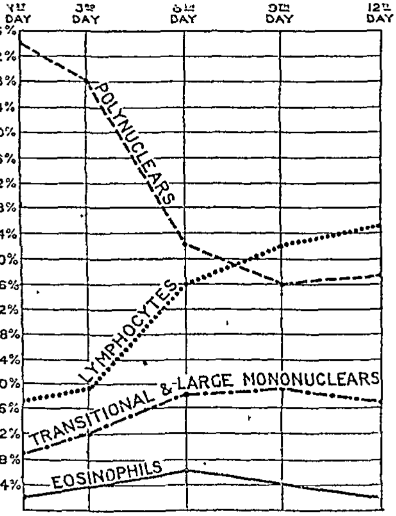
one is then apt to get a totally erroneous idea of the true state of affairs. A high percentage of any one kind of cell due to an absolute increase of its numbers in the blood makes all the other cells appear relatively diminished, although in reality their absolute number may be unaffected. What we want, then, is the absolute numbers of the different kinds of white cell in the blood at different ages. In Chart 2 these numbers are graphically represented. It will be observed that in the newly born infant the total number of leucocytes is greatly increased compared with that in the adult and amounts to about 20,000 per cubic millimetre. Further examination shows that this pronounced leucocytosis is due to a high absolute number of polynuclear cells. During the first week of life, however, this number rapidly declines, with the result that the total number of white cells falls to about one-half what it was just after birth. A second rise then sets in which persists till the sixth month but this rise is due to the appearance in the blood stream of an increased number of mononuclear cells, chiefly lymphocytes. After the sixth month the number of lymphocytes slowly declines, and with them the total number of white cells, until about the sixth year the figures characteristic of adult life are reached. Differential percentage counts bring out the same facts. (See Charts 3 and 4.)

CHART 3.



Differential percentage counts throughout life. (After Carstanjen.)

CHART 4.



Differential percentage counts during the first fortnight. (After Carstanjen.)

To summarise, then, we have to deal with a polynuclear leucocytosis most marked just after birth and gradually falling off during the first week followed by a slow rise in the non-granular cells which reaches its maximum about the sixth month but which persists in a less pronounced form throughout the whole period of infancy. The granular cells reach by the end of the first week an absolute number (about 5000 per cubic millimetre) which they maintain unaltered throughout the whole of life, whilst the non-granular cells exhibit a gradual rise up to the sixth month and have declined by the end of the third year to a number equal to that of the granular cells and not till the sixth year have they reached a stationary point—viz., about 2000 per cubic millimetre—which persists into adult life. The broad and striking conclusions to be drawn from these figures is that the blood in infancy contains an absolute excess of white cells as compared with that of the adult but that this excess (after the first week) is due entirely to a surplus of one kind of cell only—viz., the non-granular cells (chiefly lymphocytes). The significance of the initial polynuclear leucocytosis is not understood. It is a phenomenon directly associated with birth, for the blood of the fœtus during the last month of gestation contains an absolutely smaller number of white cells than that of the mother and may perhaps be due in some obscure way to the total change in metabolic conditions which birth entails. It coincides, too, with the period of active destruction of red cells already referred to and the polynuclears may perhaps be partly concerned in the removal of the débris of the latter from the circulation but that is a mere suggestion far removed from proof. The significance of the lymphocytic excess during infancy we shall be better able to appreciate when we have looked at the mode of production of the white cells as a class.

SITE OF FORMATION AND MUTUAL RELATIONS OF WHITE CELLS.

Ehrlich, whose teaching on this matter has until recently been generally accepted, drew, as is well known, a sharp line of distinction between the granular and non-granular cells of the blood. He maintained the view that the former of these are derived entirely from the bone marrow and the latter from adenoid tissue, and that the two classes of cells were absolutely distinct and never passed into one another. Recently, however, a tendency has been shown, especially by Pappenheim, Wolff, Uskoff, and others, to deny the absolutely specific nature of the granular and non-granular cells and to trace them all back to one common parent cell from which even the red corpuscles are derived. This parent type—called by Wolff a "lymphoid" cell—is almost identical in character with the large lymphocyte and is the first to appear in the fœtal blood. From it in the opinion of Wolff, all the other cells of the blood are derived according to the following scheme:—

Lymphoid cell.
Large lymphocyte. Erythrocytes. Myelocytes:
Small " (a) Basophile.
(b) Neutrophile.
Polynuclear leucocytes.
(α) With basophile granulation.
(β) " neutrophile "

In process of development a gradual differentiation of function takes place on the part of the blood forming organs in consequence of which the lymphoid cells of the marrow confine themselves to the production of granular cells, whilst those of the adenoid tissue become exclusively concerned in the production of non-granular cells (lymphocytes). The specialisation, however, is never so complete but that when a demand for a greater number of cells of one type occurs the lymphoid cells in *any* blood-forming organ are able to produce that type. We shall recur to this point, however, when we come to study the leukæmias of childhood.

A study of the development of the marrow tends on the whole to confirm the above views. Up to the fourth month of intra-uterine life the marrow, according to the researches of Hammar, has merely the characters of a very vascular embryonic tissue full of branched spindle or star shaped anastomosing cells imbedded in a homogeneous ground-work. About the beginning of the fourth month an infiltration of mononuclear leucocytes begins to appear about the middle of the diaphysis and gradually extends throughout condition of the blood in infancy is a fact of the greatest importance in the study of the blood disorders of this period of life, for as we shall see later this physiological condition may readily become exaggerated in states of disease.

The histology of the red cells in childhood need not detain us long. It is stated by many writers that they differ from those of the adult in exhibiting a tendency to inequality of size, which need not surprise us when we remember that they are probably being "minted" at enormously high speed, but such inequalities are probably of little significance. More striking is the appearance of nucleated corpuscles in the blood of the infant during the first few days of life. These are no doubt survivors of corpuscles which have been born in utero, but their complete disappearance within the first three days of life—after which they are usually no longer present—testifies to the extremely rapid blood destruction which is going on at this time.

One quality of the red cells remains to be discussed and that is their power of resistance to unfavourable conditions: in a word, are the red cells of the child more vulnerable than those of the adult? This is a question of which so far as I am aware no experimental solution has yet been attempted but it is well worthy of consideration. When we come to the study of the secondary anæmias of infancy I shall have occasion to bring forward pathological evidence in favour of the view that this greater vulnerability has an existence in fact, and if it be so it is probably to be explained by the more rapid formation of red cells in the child, a rapidity of formation which leads to their being turned out into the blood half fledged, as it were, and less capable of resisting destructive influences.

PLACE OF ORIGIN OF THE RED CELLS.

There are two stages of red blood formation during intra-uterine life: (1) an embryonic stage in which the blood-vessels and perhaps also the liver are the sites of formation; and (2) the fœtal stage proper in which red cells are formed in the liver, spleen, and bone marrow. These two stages pass into one another about the fourth month of intra-uterine life but as development goes on a process of specialisation of function takes place in which the bone marrow gradually becomes the sole site of formation. This stage is reached by the time birth takes place and I have certainly not been able to find any evidence either from my own observations or those of others that the liver and spleen take any active share in blood formation after extra-uterine existence has begun. This specialisation of function, however, is, in the case of the child, an arrangement of such recent establishment that it is easy, whenever a greatly increased demand for red cells occurs, for the monopoly of the marrow to be overthrown and for the liver and spleen again to take an active share in blood formation. Many writers believe, as a matter of fact, that this is a frequent occurrence in cases of profound anæmia in childhood. In the adult, as is well known, the territory of marrow given up to the formation of red cells is strictly limited and occupies besides the whole of the flat or spongy bones only the ends of the long bones. In the child, however, the area of the red marrow is much more extensive. Appearing at the centre of the diaphysis of the long bones about the end of the sixth month of intra-uterine life the red marrow spreads throughout the whole bone and for the whole period of infancy the entire shaft is filled with it. Gradually as growth goes on and as the primary cancellous tissue gives place to the permanent medullary cavity fat begins to make its appearance, but up to the period of puberty—in fact, until the growth of the bones is nearly completed—a considerable amount of red marrow is still present.

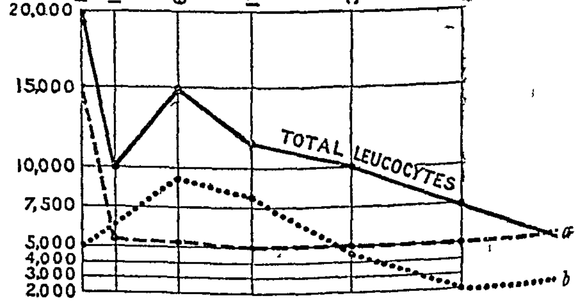
The wide extent of the red marrow in childhood is noteworthy for more reasons than one. In the first place it has a practical bearing on the morbid anatomy of the diseases of the blood at this time of life. For if one finds the whole shaft of a long bone occupied by red marrow one must not conclude, as one would be justified in doing in the case of an adult, that there has been during life an increased formation of red cells going on. That is so obvious as perhaps hardly to need to be pointed out. In the second place, it has an important physiological meaning, for if the whole of the marrow of the long bones in childhood is already occupied in the manufacture of red corpuscles there can be no reserve power of formation as there is in the adult. In the mature bones there is a large space normally filled with fat upon which the red marrow can encroach when there is any demand for a more rapid formation of red corpuscles. This takes place conspicuously in pernicious anæmia in which, as is well known, the whole of the shafts of the long bones may become filled with red marrow. But this cannot happen in the young child who, in consequence, must live more up to the limits of his blood-forming capacity. This may perhaps explain why children stand hæmorrhage badly and why it is that they are very apt to become anæmic on slight provocation. To this point we shall return in considering the secondary anæmias.

THE LEUCOCYTES.

In considering the number and variety of white cells met with in the blood of infancy it will be necessary for the sake of clearness to begin with their histological classification. Following the plan first introduced by Ehrlich and now generally adopted we can divide the white cells into the two great divisions of granular and non-granular. The first of these divisions includes the polynuclear neutrophile and eosinophile leucocytes, the characteristics of which in the child are exactly the same as in the adult and are too well known to need any description here. It is when we come to the second division that complications begin to creep in. There is no greater desideratum in hæmatology at the present moment than for some common agreement to be arrived at in the nomenclature of the non-granular white cells. One gets hopelessly confused in reading the literature of the subject to find the same cell described under several different names or the same name applied to several different cells. We badly need more light here and to have our ideas clarified as to the mutual relations of the different cells belonging to this class. Meanwhile it is the duty of everyone who writes on the subject to define clearly the meaning of the terms which he intends to employ. I propose throughout these lectures to adopt the following classification of the non-granular cells of the blood:—

1. *Lymphocytes*, meaning cells about the size of, or rather smaller than, a red corpuscle with a deeply staining nucleus which occupies nearly the whole of the cell and only a small margin of feebly basophile non-granular protoplasm.
2. *Large lymphocytes*, being cells larger in size than a red corpuscle, with a nucleus which stains more diffusely than in the ordinary lymphocyte and a small ring of basophile protoplasm. These cells are not found normally in the blood of the adult but I believe that they are always present though in small number in infancy. All stages can be recognised between small and large lymphocytes. The large lymphocyte is probably a less mature form than the small.
3. *Large mononuclears*, cells varying from 8 to 12μ in diameter with a large round or oval nucleus which stains rather faintly and a relatively broad margin of clear protoplasm which stains only "greyish" with methylene blue.
4. *Transitionals*, which resemble the above except that the nucleus is deeply indented.

CHART 2.



Absolute number of leucocytes per cubic millimetre at different ages. *a*, Polynuclears. *b*, Lymphocytes.

As regards their *character* it will be noticed that these cells are, with the exception of the large lymphocytes, identical with the white cells commonly met with in the blood of the adult. It is when we come to consider their numbers, however, that striking differences become manifest and here I should like to point out, as has already been done by Phear, that it is not sufficient to make merely a differential percentage count of the white cells in the blood, for cent. of other cells; and in a third (age nine years) 79 per cent. of polynuclears and 20 per cent. of non-granular forms. There is here, except in one instance (the second), no marked departure from the normal and in that case there was probably simple secondary anæmia present such as is met with in rickets. I know of no observations on the blood in Mongolism although the widespread malformation met with in that interesting condition might have been expected to draw attention to it. In a few well-marked cases which I have examined I found, however, no striking or characteristic change.

Turning to the third of the congenital malformations mentioned above—infantilism—one asks one's self: Does the blood in this condition preserve, like the body generally, its infantile condition? I am aware that the term infantilism is one of rather indefinite significance and that it is difficult in particular to mark it off sharply from dwarfism on one hand and infantile myxœdema on the other. All the more on that account, however, is a study of the blood likely to prove of interest and seeing that it possesses throughout the infantile period of life such marked characteristics—characteristics already fully described—we possess in it a criterion for the maintenance or otherwise of a truly infantile state of body not easily to be found elsewhere. I have examined the blood in four cases which were believed to be examples of this condition in none of which was any general anæmia present and which had all reached an age far beyond that at which the blood normally assumes the adult characters.

The first of these, a gi
and mental characteristi
the following differential

growing." Her height
2 stones 10½ pounds and
child aged about five y
hair was rather coarse and dry, and her voice was deep and harsh but there were no signs of cretinism. She was childish and backward mentally but not in any sense imbecile. A blood film showed the presence of 60·4 per cent. of uninuclear, non granular cells, and 39·6 per cent. of polynuclears.

It will be observed that in the first two and in the last of these cases the blood exhibited the marked excess of non-granular cells characteristic of infancy. In the third it was of the normal adult type. It may be that in the condition of the blood in these four cases we possess a means of classification and that whereas three of them should be regarded as purely infantile—i.e., in a state in which there is still the potentiality of growth—the third must be regarded as an example of development which is not so much arrested as proceeding on abnormal lines. We certainly want more information regarding possible delays in the assumption of the adult type of blood and their significance. Normally, as we have seen, this should happen somewhere between the third and sixth years but there is every reason to believe that the change is sometimes postponed until after that period. Roughly speaking, and so far as I have been able to observe, the feebler and more delicate the child the longer is the infantile type of blood maintained. On the side of the blood-forming organs this must correspond to a prolongation of the usual period of maximum activity of the adenoid tissue and there is reason to believe that such an occurrence is always an indication of delicate health and a feeble power of resistance but I shall return to this point when I come to speak of the condition known as "lymphatism."

2. *Congenital anæmias.*—Clinically, one meets from time to time with infants who have been markedly anæmic from birth. Putting aside those cases in which injudicious feed-

A differential count show
of mononuclears (mainly l
per cent. of myelocytes, and 1 per cent. of mast cells. There were five normoblasts to every 100 white cells. The child subsequently developed some enlargement of the spleen.

It seems natural in such cases to try to connect the anæmia of the child with defective health on the part of the mother. Such an explanation, however, cannot always or indeed often be advanced. I have not found that the health of the mother during her pregnancy has been specially bad in such cases nor that she has herself suffered from anæmia. One has to remember, too, that the blood-forming functions of the fœtus are quite independent of those of the mother. This is certainly true at all events of the formation of blood cells. A striking illustration of it is found in the case of women suffering from myelogenous leukæmia who yet give birth to perfectly healthy infants. Of such an occurrence many cases are now on record and I have seen at least one well-marked instance of it myself. As regards the chemical constituents of the blood, however, it is by no means certain that such independence exists. Bunge has shown that the child comes into the world with a store of iron in the liver which is derived from the blood of the mother and serves as a supply of that metal throughout the earlier months of life. In some of the cases of congenital anæmia it would seem that this store is insufficient. This seems particularly apt to happen in the case of twins in which there is as it were not enough iron to go round and one twin or both suffers from a deficiency in consequence. In such a case the anæmia takes the form of a deficiency of hæmoglobin rather than of the red cells as a whole.

It is interesting to note that in two of the above cases the mother volunteered the statement that the appearance of the anæmia had been preceded by severe and prolonged jaundice, evidently an exaggerated degree of the ordinary icterus neonatorum. It may be that in such cases there has been an unusual amount of blood destruction, an amount which it has been beyond the power of the blood-forming organs fully to compensate or which has exhausted the available reserve of iron in the liver. When a defective supply of iron to the blood forming organs is the cause of the anæmia steady improvement follows the administration of iron by the mouth, but in other cases of anæmia dating from birth even the most persistent treatment with iron fails to effect any improvement. In such cases it is possible, though in the absence of more post-mortem evidence one does not wish to be too dogmatic about it, that there is a congenital defect in the red marrow and in consequence an insufficient formation of red cells. Muir[1] has recorded such deficiency of marrow coming on in a boy, aged 14

---

[1] A Case of Purpura and Intense Anæmia with Marked Deficiency in the Red Bone Marrow, Brit. Med. Jour., Sept. 29th, 1900.

resist the conclusion that the provision for the manufacture of red cells was defective.

Of an exactly opposite nature to such cases are those in which there is an excess of red corpuscles and of hæmoglobin in the blood, as is seen in *congenital cyanosis.* I do not propose to discuss the supposed reasons for the presence of a surplus of red cells in these cases but would merely point out that examination of them after death has shown an undue degree of activity on the part of the blood-forming organs and a persistence of the fœtal method of intra-capillary blood formation, especially in the thymus.[2]

PRIMARY ANÆMIAS.

1. *Chlorosis.*—If we define chlorosis as most authors seem inclined to do as a condition of anæmia exhibiting a marked relative deficiency of hæmoglobin but occurring only in young women then such a condition can have no place amongst the anæmias of infancy. There can be no doubt, however, that cases are met with in childhood which show at least a markedly chlorotic type of blood along with many of the other signs characteristic of the classical type of the disease. The following are two typical examples.

CASE 1.—A girl, aged one year and seven months. She was a fat rickety child who got little animal food owing to the poverty of the parents. Her complexion was waxy. The spleen was just palpable; hæmic murmurs were present. The blood contained 4,000,000 red cells and only 20 per cent. of hæmoglobin. There was some poikilocytosis and a few normoblasts were present. Under treatment with iron the hæmoglobin rose in a month to 60 per cent.

CASE 2.—A girl, aged three years. She had been fed on the breast till 18 months old. Since then she had been rickety. Her complexion was chlorotic. Her spleen was palpable; hæmic murmurs were present. Red cells numbered 5,000,000, white 13,000, and hæmoglobin 31 per cent. The red cells were regular in size and shape. Under full diet and iron in large doses the hæmoglobin rose in six weeks to 62 per cent. and the child was discharged in good health.

It may be objected that these are simply examples of secondary anæmia associated with rickets. Such an objection I should not care to dispute. What I wish to emphasise, however, is that one does meet in infancy with anæmias characterised by blood of markedly chlorotic type associated with the greenish complexion, hæmic murmurs, and other well-recognised symptoms of the disease as it occurs in young women. Nor need such an occurrence surprise us. The blood of infancy is, as we have seen, normally poor in hæmoglobin compared with that of the adult and the presence of any factor which renders the formation of hæmoglobin still more difficult may readily lead to the appearance of a chlorotic form of anæmia. Such a factor is to be found, I believe, in a deficient supply of iron in the food. Human milk is at best but poor in iron, containing only from 3·5 to 7 milligrammes of the metal per litre (Friedjung[3]) and bad health in the mother may lower this proportion still further. The balance of iron required for purposes of blood formation is made up, as we have seen, from the store of it normally contained in the liver, but if the period of nursing—or of purely milk feeding—is unduly prolonged this reserve becomes exhausted and a deficiency in hæmoglobin results. Cases such as have been described seem specially apt to occur, therefore, amongst children who have been fed at the breast for a protracted period or who after weaning have been supplied with a diet in which animal food is but poorly represented. Such a diet is, of course, just such as is also apt to produce rickets and the correct view to take of such cases is, I believe, that the anæmia is not secondary to the rickets but that both the rickets and the anæmia are the common consequence of unsuitable food. For proof of this one would point to the striking improvements which such patients exhibit when put upon a diet rich in iron and especially when salts of iron are simultaneously given by the mouth.

2. *Pernicious anæmia.*—When we come to consider the question of pernicious anæmia in childhood we are again met by the difficulty of definition. I need not remind you how divided authorities are in this matter, some regarding the absence of any discoverable cause as the criterion of the disease, others basing its diagnosis upon the characters of the blood. These difficulties in the way of recognition of the disease, great as they are in the adult, are greater still in the child. For at this time of life any secondary anæmia may take on a grave form marked by pronounced poverty of red cells, great variability in their size and shape, and the presence of numerous nucleated forms. The relative lymphocytosis, too, which is generally agreed to be a characteristic of the blood in pernicious anæmia is of little assistance in the diagnosis in infancy, during which, as we have seen, such a condition is of normal occurrence. Nor is it easy to recognise pernicious anæmia in infancy from its morbid anatomy, for one of its most striking pathological features—the replacement of the yellow marrow by blood-forming tissue—is found in the normal child. Evidences of increased blood destruction, such as the accumulation of iron in the liver, would be of more value, for, so far as I have seen, it is not found even in the severe secondary anæmias of childhood, but unfortunately this has not always been sought for in the reported cases. Whatever criterion we accept as identifying the disease it is generally admitted to be extremely rare in childhood. Rotch states that out of more than 2000 cases below the age of two admitted to the Infants' Hospital in Boston there was not one of true pernicious anæmia and I have searched the records of the Hospital for Sick Children, Great Ormond-street, for one in vain. In Table I. I have collected from all the available literature cases which have been published as examples of pernicious anæmia occurring in childhood.

It will be observed that they amount to not more than 11 in all, of which only five are at all probably genuine, and of these but one falls within the period of infancy. As in the adult, males appear to be much more frequently affected than females.

The rarity of pernicious anæmia in childhood is a surprising fact. Recollecting the vulnerability of the blood at this time of life and the ease with which injurious influences seem to affect it one would have expected, if pernicious anæmia be really due to the excessive destruction of blood by a poison, as most authorities seem to think, that it is at this time of life above all others that it would be most apt to occur. If, again, we have to deal in this disease with a resumption of the fœtal mode of blood formation with the appearance of megaloblasts in the blood or, at all events, in the marrow, as Ehrlich teaches, surely it is in the child who is but so little removed in time from the fœtal state that such a retrograde metamorphosis would be most prone to manifest itself. Nor are children exempt from those special destructive influences which have sometimes been invoked to explain the disease. Oral sepsis is a frequent and familiar condition in them and is believed by many to be a common cause of secondary anæmia; the parasitic anæmias also which may so closely simulate the genuine disease find striking illustration even in the earliest years of life (see cases of bothriocephalus anæmia published by Schapiro[4] and by Podwissotzky[5]). Whatever the explanation of the comparative immunity of young children to pernicious anæmia may be it is a striking fact in the natural history of the disease which must always be reckoned with in any attempt to account for its etiology.

SECONDARY ANÆMIAS.

The characters of the blood and blood-forming organs in infancy are such as to render the young child peculiarly apt to become anæmic under the action of deleterious influences of various sorts. To this form of anæmia the term secondary or symptomatic anæmia may conveniently be applied. Such deleterious influences may act either upon the blood-forming organs, rendering them less capable of forming blood, or upon the blood itself leading to its increased destruction, or both modes of action may coexist. However produced, secondary anæmia in early childhood is apt to assume a severity rarely met with in adult life and in the most pronounced forms may present a blood picture which in the adult would justify a diagnosis of pernicious anæmia. One can distinguish, however, several grades of symptomatic anæmia The hæmoglobin seems always to suffer first and in the mildest cases the blood has simply a slightly chlorotic character. This is not surprising when one remembers the fact, already insisted upon, that the infant's blood is normally poor in hæmoglobin and that the marrow seems only capable of forming it in limited amount. When the injurious influences are such as actually to destroy the red cells or seriously to impair the power of the marrow to form them the blood exhibits a poverty of red corpuscles in addition to a low percentage of hæmoglobin. In such

TABLE I.—RECORDED CASES OF PERNICIOUS ANÆMIA IN CHILDHOOD.

No.	Author and reference.	Sex and age.	General clinical characters.	Condition of the blood.	Result.
1*	Kjellberg (Archiv für Kinderheilkunde, v., p. 181; 1884).	M., 5 years.	Marked debility, lemon-yellow tint, hæmic murmurs, retinal hæmorrhages, and all the classical symptoms	Red cells, 767,000, falling to 571,000, no further description.	Death in 16 weeks. Post-mortem examination was negative.
2	Steffen (Jahrbuch für Kinderheilkunde, xxviii., p. 444; 1888). Gives references to other cases of doubtful authenticity.	F., 16 months.	A rickety child, with general anæmia, but no splenic enlargement.	Red cells one third of normal, pale but with no alteration of shape, white cells diminished.	Death. Post-mortem examination.
3	Escherich (Wiener Klinische Wochenschrift, 13 and 14, 1892. Contains references to previous alleged cases).	M., 4 years.	Extreme pallor, the spleen was not enlarged, there was some enlargement of the glands in the left side of the neck and left axilla.	Lowest red count 575,000; slight poikilocytosis, megalocytes, but no normoblasts, hæmoglobin from 12 to 15 per cent; white cells diminished, lymphocytes predominating.	Death. *No post mortem* examination.
4*	Mott (Practitioner, August, 1890).	M., 11 years.	Ill eight months, frequent vomiting, lemon yellow tint, retinal hæmorrhages, &c.	Red cells, 800,000; hæmoglobin, 20 per cent.; marked poikilocytosis, micro and macro-cytes, few normoblasts	Death. Post-mortem examination showed typical appearances of pernicious anæmia.
5	Monti and Berggrün (Die Chronische Anämie im Kindesalter, Leipsic, 1892).	M., 6½ months.	A pale, rickety child, with a history of congenital syphilis; the spleen was much enlarged.	[illegible]	Death. No post mortem examination.
6	Demme (quoted by Monti and Berggrün, op. cit.).	M., 3 months.	Very anæmic since six weeks old; the spleen was not enlarged.	Red cells, 800,000, hæmoglobin from 28 to 30 per cent, poikilocytosis, several megaloblasts	Death. Post mortem examination.
7	D'Espine and Picot (Revue de Médecine, 1890, p. 859).	F., 2 years.	Pronounced pallor and tendency to hæmorrhages coming on after previous good health, there was no enlargement of the glands or spleen.	Not examined	Death after a month. No post-mortem examination, but the authors think that leukæmia could be excluded.
8	Ibid.	M., 13 years.	Gastro intestinal symptoms (vomiting, diarrhœa, and colic) predominated, œdema of the limbs; the liver and spleen were not enlarged; there was frequent epistaxis.	" "	Death. Post mortem examination was negative.
9*	Theodor (Archiv für Kinderheilkunde xxviii., p. 321, 1901).	M., 11 years.	Ill for one year with all the typical symptoms and appearances.	Red cells very pale, marked poikilocytosis, many megalocytes, 24 rising to 93 per cent. of normoblasts	Death.
10*	Rotch and Ladd (Archives of Pediatrics, September, 1901).	F., 9 months.	Great pallor and some general œdema; there was no enlargement of the spleen.	Red cells, 1,088,000; hæmoglobin, 20 per cent, white cells, 18,800, "microscopical characters typical of pernicious anæmia" (Cabot).	Doubtful.
11*	Goodell (Scottish Medical and Surgical Journal, February, 1902).	M., 11 years.	Anæmia with hæmorrhages from the mucous membranes but none in the fundi; the spleen was not enlarged.	Red cells, 295 000, hæmoglobin, 5 per cent, white cells 20,000, four megaloblasts and 25 normoblasts to 1000 white cells	Death. No post-mortem examination.

* The cases marked with an asterisk are probably genuine.

TABLE II.—CASES OF INFANTILE SCURVY TREATED WITHOUT ALTERATION OF DIET.

No.	Sex and age	Symptoms.	Diet.	Treatment and result.
1	M., 9 months.	Sponginess of the gums and general tenderness of the bones.	Condensed milk and a tinned food.	Half an ounce of fresh orange juice daily. After a week the tenderness was diminished, the gums were as before, the diet was then changed
2	F., 6 months	Sponginess of the gums, thickening and tenderness of the lower end of the left femur and tibia.	Boiled milk, with a tinned farinaceous food.	Half an ounce of sterilised fruit juice daily. After a week all the symptoms were greatly improved, the diet was changed.
3	F., 10 months.	Sponginess of the gums, tenderness of the lower end of the left femur.	Condensed milk and Mellin's food.	Half an ounce of dialysed fruit juice daily. After a week the tenderness was very much less. There was still some sponginess of the gums, the diet was then changed
4	M., 7 months	Sponginess of the gums, thickening and tenderness of both femora.	Condensed milk and a tinned farinaceous food.	I [illegible] improvement in every [illegible]
5	F., 8 months.	Moderate sponginess of the gums, the legs were tender but there was no thickening.	Condensed milk and a tinned food.	40 grains of calcium citrate daily produced no improvement in a week After ten days' treatment with malate of potash the tenderness had almost gone and the sponginess was much less. The diet was then changed.
6	M., 8 months.	Sponginess of the gums, thickening and tenderness round the right knee.	Condensed milk and a malted food.	Citrate of potash in small doses produced no change after four days. The diet was then altered.
7	F., 12 months.	Sponginess of the gums and general tenderness,	Boiled milk.	Malate and tartrate of potash (10 grains of each daily) After a week all the symptoms had greatly improved. Raw milk was then given.
8	M., 11 months.	Considerable sponginess of the gums, tenderness but no swelling of the legs.	Condensed milk and nursery biscuits.	Malate of potash 40 grains daily As there was no improvement after four days ordinary treatment was begun.

circumstances irregular varieties of red cells (poikilocytosis) and nucleated forms very often make their appearance. It is the pronounced tendency for these abnormalities to develop which indeed specially distinguishes the secondary anæmias of infancy from those of adult life. Acting as it does even in normal conditions close up to the limit of its functional capacity and being unable, for reasons already mentioned, to increase its power of blood formation by a process of hyperplasia, the red marrow of the child when increased demands are made upon it for a greater production of red cells can only meet that demand by a more rapid division of its constituents instead of by extending the area of production over a wider territory. Such rapid production is apt to lead to imperfect formation of corpuscles and to their being turned into the blood stream in a "half-fledged" condition as it were, with their nuclei still present and with a feeble power of resistance. Hence it is that the presence of normoblasts and of poikilocytosis are such striking features in the secondary anæmias of childhood and the younger the child—i.e., the less the power of hyperplasia the marrow possesses—the more readily do such features make their appearance.

In the severest forms of secondary anæmia leucocytosis is apt to develop in addition to diminution of hæmoglobin and red cells. *In many cases this is due to the presence of some* complicating disease, of which perhaps broncho-pneumonia is in practice the most common. In such a case the leucocytosis assumes the ordinary polynuclear type. In some instances, on the other hand, and these especially in young infants, secondary anæmia is accompanied by an exaggeration of the normal excess of lymphocytes. I think, however, that the frequency with which this occurs has been overstated. Putting aside cases of severe rickets with splenic enlargement, to which we shall return in another lecture, it seems to be chiefly in anæmias associated with chronic gastro-intestinal disturbance that lymphocytosis is most apt to occur. One is tempted to suppose that there is here an overproduction on the part of the adenoid tissue scattered throughout the abdominal tract, an exaggeration as it were of the normal digestive leucocytosis. If the lymphocytes in this situation are really normally concerned—as many people believe—in the absorption of food from the intestine it is not straining the imagination too far to suppose that any condition which renders difficult the process of absorption may be compensated by an over-production of these cells. Their increased numbers may enable as much as possible to be saved from the wreckage of food which is being swept on too fast into the lower bowel. The excess of lymphocytes in the blood in such a case would exactly correspond to the excess of red corpuscles met with in cases of cyanosis. In both instances over-production of the cell concerned is nature's way of overcoming obstacles in the way of its fulfilling its normal functions. But this, of course, is pure speculation.

It would be impossible to deal in any detail with the numerous injurious influences which may lead to the development of symptomatic anæmia, nor indeed would anything be gained by attempting to do so, but one or two typical illustrations may be selected. Of influences which probably act chiefly on the blood-forming organs malnutrition is one of the commonest and best marked. The most striking examples of the action of this influence which have come under my observation have been in the case of children who have been fed too long at the breast or who have been kept on a purely milk diet far beyond the time at which mixed feeding should be adopted. The following is a pronounced example of such a case.

A boy, aged two years and three months, a twin, born at the full time, had been feeble since birth. He had always been bottle fed and when he came under observation was getting two quarts of milk a day without any other food. He exhibited extreme pallor without any sign of rickets and no enlargement of the spleen. There was a loud systolic murmur over the præcordia, the blood was very watery and contained 1,692,000 red cells, 4000 leucocytes, and 17½ per cent. of hæmoglobin. There were 60 normoblasts per cubic millimetre but no poikilocytosis. Under treatment with ordinary mixed diet and full doses of iron the number of red cells rapidly rose to 3,500,000 and the hæmoglobin to 43 per cent.

The special defects of the diet which are doubtless responsible for the production of the anæmia in these cases are: (1) poverty in iron; and (2) deficiency in proteid. The raw material for the production both of hæmoglobin and of red cells being thus lacking poverty of blood results. As both these defects are specially marked in a purely milk diet it is not to be wondered at that children who have been fed on such a diet too long should exhibit secondary anæmia in a striking form. To this point I have already referred in the discussion of chlorosis. There can be no doubt, too, that a similar cause is a potent factor in the production of milder degrees of anæmia in later childhood. Here is an illustration.

A girl, aged five years, had always been a pale child, but owing to the death of her mother had for some time been badly cared for and insufficiently fed. She was very chlorotic looking, had a just palpable spleen, and also loud hæmic murmurs. The blood contained 2,400,000 red cells, 15,000 white cells, and 40 per cent. of hæmoglobin. There was marked poikilocytosis but there were no nucleated red cells and of the white cells polynuclears predominated. She was put on a diet rich in animal constituents and full doses of iron and left hospital entirely cured.

I have selected here a pronounced example but such cases in a minor degree are met with every day. They are the peculiar product of poverty which necessitates the consumption of a diet which is not so much deficient in quantity as defective in quality, lacking especially those more expensive animal constituents which can alone insure a sufficient supply of proteid which is so essential in the building up of blood as of all tissues. Slight anæmia from this cause is a potent factor in the chronic ill health so often seen in the children of the working classes, particularly in large towns where the blood-forming functions are still further depressed by the absence of sunlight and fresh air. Nor should such slight degrees of anæmia be neglected, for although they may be, and usually are, fully recovered from later when a more generous diet is obtainable yet their effects may be irreparable. For it must not be forgotten that it is not a matter of indifference when the tissues and organs during the susceptible years of growth have been bathed with a poor and watery fluid instead of with rich and fruitful blood. Impairment of growth and development, shrinking of body and backwardness of mind, cannot fail to be the consequences and those to whom the present state of the national physique is a source of anxiety would do well, I believe, to look to this as a potent source of possible deterioration.

Of influences which lead to secondary anæmia by causing an increased destruction of blood the best examples are to be found amongst the acute infective diseases. The vulnerability of the blood in childhood so often referred to renders it peculiarly liable to suffer from the influence of the toxins of such diseases. Though almost all the acute specific fevers show their influence upon the blood in children by a fall in hæmoglobin which sets in just after the temperature has fallen and is only restored during later convalescence,[6] yet the destructive power of some toxins appears to be much greater than that of others. The rheumatic poison seems to be peculiarly potent in this respect. Children rarely fail to exhibit a marked degree of anæmia after an attack of acute rheumatism especially, I think, when accompanied by peri- or endo-carditis. Every fresh outbreak of the disease during convalescence is apt to signalise itself by a deterioration of the blood. This rheumatic form of anæmia which must be familiar to every clinical observer has been specially studied by Dr. A. E. Garrod who has shown that the fall in the red corpuscles in these cases is usually very rapid and may easily amount to 1,000,000 in the course of four or five days. It is interesting, too, to note that sudden and marked falls in the hæmoglobin may occur independently of those in the red cells. The destruction of blood in these cases bears no necessary relation to the height of the fever nor is it influenced by the administration of salicylates. The destruction of red cells is usually speedily made good after the temperature has fallen, but in some cases the diminution of hæmoglobin persists far into convalescence and long after the patient's condition has improved in every other respect. Diphtheria is another of the acute infectious diseases which is apt to be attended by severe blood destruction. It is also characterised by a tendency for myelocytes to appear in the blood—a sign always of bad prognostic omen. The influence of the toxins of the pyogenic organisms is seen in the anæmia associated with oral sepsis in childhood to which Hollopeter[7] has specially drawn attention and in the pronounced anæmia which results from long-standing suppuration. Of mixed causes of secondary anæmia in childhood the syphilitic cachexia, tuberculosis, and chronic diarrhœa may be taken as examples. These probably act both by increasing blood destruction and by interfering with its formation. In these and in all secondary anæmias there is no characteristic type of blood and the extent and degree of destruction are of more value in gauging the intensity of the disease and in forming a prognosis than in making a diagnosis.

INFANTILE SCURVY.

The condition of the blood in cases of infantile scurvy raises questions of great interest and importance. The general pathological [illegible] worked out by those [illegible] Dr. W. B. Cheadle and [illegible] nothing of importance to be added from that side. It will be admitted, however, that we are still very much in the dark as to the actual change in the blood which is present in this disease. Now, in the first place it may be remarked that the microscope affords us no help here. An examination of the blood in cases of scurvy shows that it exhibits merely a varying degree of that secondary anæmia of rather chlorotic type which is so frequent in rickets and other conditions of impaired nutrition. Nor does histological examination of the marrow which I have been able to carry out in two cases reveal any characteristic changes. We are driven, then, to study the question from the chemical point of view. It will be obvious that this is an investigation attended by great difficulties. One cannot obtain a sufficient quantity of blood to subject it to accurate chemical analysis and accordingly one is compelled to study the subject indirectly. In the course of the last few years I have tried, at the suggestion of Dr. Garrod and as opportunity offered, to arrive, by a process of therapeutic experiment, at an idea of what the chemical fault in the blood of these cases is. My progress towards a solution of the problem has been slow, for cases of infantile scurvy are not numerous and not all of them are suitable subjects for such observations as I am about to describe, but it may be worth while to put before you the results so far as I have gone in the hope that they may lead to more extended observations on the same lines by others.

It will be generally conceded in the first place that infantile scurvy is the result of a faulty diet. The first question that arises then is this: Is the fault a positive or a negative one? That is to say, is there present in the food some constituent which it should *not* contain, or is there absent from it or present in insufficient amount one of its normal ingredients? To this question the general study of the etiology of the disease has not afforded any satisfactory reply. It has shown only that the vast majority of cases develop when the child is being fed upon a diet which is deficient in fresh constituents, particularly in fresh milk. As to how it is that such a diet produces the disease no explanation is forthcoming. It has been referred by some to the presence of poisonous constituents (ptomaines) in tinned foods, a view which as regards adult scurvy, at all events, [illegible] e experiments [illegible] referred the [illegible] ce in them of some mysterious ferment. The first step, then, must be to see whether, leaving the diet under which the disease developed alone, one can, by the mere addition of certain constituents to it, effect a removal of the symptoms. Fruit juice is the material which one naturally thinks of adding and in order to elimininate the ferment theory I have given it in a sterilised form. In Case 2 of Table II. this was added to the diet, no other change being made, and the result showed that it had a distinctly curative influence.

The inference to be drawn from this observation and from that on Case 1 is that the fault in the diet of scurvy is one of omission and not of commission, in that fruit juice contains something which the blood in this disease lacks and that this ingredient is of an "unorganised" nature. The next step was to administer the constituents of fruit juice separately and so to arrive by a process of exclusion at the particular ingredient concerned. By means of dialysis the crystallisable were separated from the uncrystallisable constituents of the juice and the dialysate was evaporated [illegible] iginal quantity of [illegible] not included in [illegible] uncrystallisable or [illegible] ative effect. The [illegible] d proved to have a distinct [illegible] tion seeme [illegible] contained [illegible] proof of th [illegible] administration of an artificial mixture of the vegetable salts found in fruit juice is also followed by cure. Here, however, [illegible] citrate, [illegible] anything like such good results as with the natural juice (see Cases 5, 6, 7, and 8). That these salts, however, have, even in their artificial form, a power of restraining the disease I think there can be no doubt; and my friend Dr. John Thomson tells me that he has seen a case in which scurvy was kept in check so long as citrate of potassium was being administered for other reasons.[8] It may be that these salts are less active in their artificial form than in that in which they occur in the natural juice, just as it is well known that a natural mineral water is often more active than any artificial imitation of it. At all events, I think the conclusion is provisionally justified that the defect in the blood which causes the symptoms of scurvy is a poverty in vegetable salts, a conclusion which I need not point out is in no way a novel one, though it has never, so far as I know, been put to any systematic test.

A priori reasoning would lead to the conclusion that the citrates are the vegetable salts chiefly concerned. It must never be forgotten that fresh milk is surprisingly rich in citric acid. It has been calculated, indeed, that three pints of it contain from 50 to 60 grains of citrate, or about as much as is contained in an ounce of lime juice. In milk the citric acid is combined with calcium as citrate of lime. Corlette, in an interesting paper read before the British Medical Association in 1900, has shown that the calcium citrate of milk occurs in the amorphous and more soluble form, its solution being aided by the presence of phosphates. When milk is boiled the amorphous is converted into the crystallisable form of the salt which is less soluble and separates out. The mere boiling, and *a fortiori* the sterilisation, of milk therefore causes it to become poorer in citrates than it ought to be, and to this he attributes the development of scurvy when such milk is exclusively used. Ingenious and simple though this explanation is, it cannot yet be regarded as proved. I have certainly found that the artificial administration of calcium citrate is of even less therapeutic power in scurvy than are the artificial salts of potash (Case 5). In any case it must be admitted that the hypothesis of a deficiency of vegetable salts in the blood does not bring us much nearer an understanding of how it is that the hæmorrhages and other characteristic symptoms of the disease are brought about. [illegible] coagulability of the blood [illegible] nd. Whatever may be the [illegible] of the blood in scurvy of [illegible] any way lessened in the infantile form of the disease. I have tested this point in five well-marked cases, using Wright's coagulometer, with the following results:—

Age	Coagulation time.
Eight months	3¾ minutes.
Eleven „	4½ „
?	4¼ „
One year	5¼ „
One „	4 „

This gives an average coagulation time of about four and one-third minutes which closely corresponds with the normal. One effect, however, which one would certainly expect to ensue upon a [illegible] the blood is a [illegible] diminished alkal [illegible] I have not mys [illegible] informs me tha [illegible] cases with the [illegible] the reaction of [illegible] alkalinity actually exists. Such an occurrence would not be at all at variance with the results of general clinical observation on the etiology of the disease. Everyone must have seen cases of scurvy in which the mere stoppage of the use of a tinned food without anything being substituted for it or other change made in the diet has been followed by the happiest results. Now the cereal foods, as Wright has shown,[9] certainly yield a more acid ash than milk and what happens probably in such cases is that there is a disturbance of the proper balance of acid and alkaline constituents in the blood, a balance which is readjusted when the supply of the more acid salts is withdrawn. Wright has established this in the case of adult scurvy by an examination of the blood of soldiers who suffered in the siege of Ladysmith[10] and has, as already stated, found a similar condition of the blood in cases of infantile scurvy. It seems likely, therefore, that it is upon such lines as those indicated above that the explanation of the ultimate cause of the disease must be sought.

---

[8] Dr. Thomson writes that the case alluded to was that called "Baby B." in his paper on Acute Pyelitis in Infants (Scottish Medical and Surgical Journal, July, 1902). She had been brought up mainly on sterilised milk and cream mixture; but to this two meals of gruel and one of Nestle's food had been added for a short time. She had [illegible] thriven well enough till nine and a half months old [illegible] movement of [illegible] her symptoms [illegible] red and swollen. [illegible] sed milk was continued and citrate of potash was [illegible] the pyelitis which soon disappeared. A few days after it was stopped, however, distinct scorbutic symptoms appeared—viz., marked sponginess of the gums and large bruises on both shins. Under the usual dietetic treatment she recovered rapidly.

The Oliver-Sharpey Lectures

ON

RECENT STUDIES ON THE TISSUE-LYMPH CIRCULATION.

Delivered before the Royal College of Physicians of London on April 12th and 14th, 1904,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE II.[1]

Delivered on April 14th.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—The last lecture was almost entirely devoted to the study of the effects of digestion on the tissue-lymph circulation. We have now to consider the influence of exercise, fatigue, rest, sleep, respiration of gases, internal secretion, temperature, and gravitation.

THE EFFECTS OF EXERCISE.

The effects of muscular action have been studied, first, during its continuance; secondly, immediately on its cessation; and thirdly, for some time after the termination of the exercise. Each of these three sets of observations has yielded distinctive facts which, when observed collectively, have invariably followed the same order. It is therefore obvious that observation made during any one of these stages only must furnish an incomplete picture of all the effects of exercise. Most observers, because of the difficulty of recording the blood pressure accurately while exercise is in progress, have made their observations only when muscular action ceases. The fundamental effects of exercise on the blood pressure may be readily studied in an epitomised form by placing the pad of the hæmodynamometer over a small *superficial artery, like the superficialis volæ* and then throwing all the muscles into a state of tension for 60 seconds (the arm on which the observation is made being excluded from the contraction). In Fig. 6 you observe that the complete blood pressure curve of muscular contraction is made up of two elevations (A) and (C), separated by a fall (B), which is just as decidedly below the normal pressure as the second rise is above it. The first elevation (A) is synchronous with the tension, the second (C) appears after the muscles are relaxed. Now these oscillations of the arterial pressure are all seen on a larger scale in ordinary exercise, each stage being, of course, prolonged in proportion to the duration of the exercise. The primary rise is invariably followed by a gradual fall, even during the continuance of the exercise, and by a rapid and decisive fall on its cessation; and that fall is succeeded during rest by a second rise. Sir Lauder Brunton and Dr. J. W. Tunnicliffe, some of whose experiments were made in Professor Mosse's laboratory, are, I believe, the only observers who have furnished trustworthy data on the *arterial pressure in man both during* muscular movement and immediately after its cessation, and their data accord with my own.[2] The secondary rise of blood pressure which I have invariably found to supervene during rest after exercise does not, however, seem to have been recognised by other observers unless we conclude that Marey recorded it when he found that the pressure in the carotid artery of the horse after falling six millimetres of mercury immediately following a run of ten minutes subsequently rose seven millimetres of mercury above its original height.

Exercise increases the exudation of tissue lymph. This fact is indicated by the differential readings of the blood taken either during a sustained muscular contraction or immediately after exercise. Inasmuch as lymph is rapidly removed, being absorbed on the cessation of exercise, the observation should be made without delay, for in from five to 15 minutes after walking or other forms of exercise the samples of blood taken before and after compression will generally read alike, showing that the lymph has disappeared.

How are these effects of exercise produced? According to Ludwig and Gaskell[3] during a short tetanus (such as a sustained contraction of 60 seconds) the flow from the efferent vein of the muscle after the first spurt of blood may fall to practically *nil.* It would seem that muscular contraction causes partial or temporary occlusion of the intramuscular arteries and arterioles and that this increase of peripheral resistance, along with reflex cardiac stimulation, will go far to explain the rise in the arterial pressure. At the same time the capillary pressure within the muscle will fall and lymph will not be exuded. But the state of the circulation is different in the non-muscular parts, for all the blood pressures (arterial, venous, and capillary) are markedly raised during the sustained tension of the muscles. Hence the effusion of lymph in the finger. On the other hand, when the contraction ceases the intramuscular capillary pressure at once rises and lymph will be effused into the muscles in the intervals between successive contractions. That the muscles when relaxed after contraction become full of blood is shown by the work of Ludwig and his pupils, by Chauveau and Kaufmann, and also by Sir Lauder Brunton

[10] THE LANCET, August 25th, 1900, p. 565.

[1] Lecture I. was published in THE LANCET of April 30th, 1904, p. 1175.

[2] Remarks on the *Effect of Resistance Exercises* upon the Circulation in Man, Local and General, by Sir Lauder Brunton and Dr. J. W. Tunnicliffe, Brit. Med. Jour., Oct. 16th, 1897.

[3] Ludwig's "Arbeiter," 1877.

and Dr. Tunnicliffe, who have furnished graphic evidence of the dilatation of the intramuscular arteries which follows muscular contraction.[4]

In the first lecture I demonstrated by the effect of muscular tension on the arterial pressure that when the lymph is being effused the contractibility of the muscles diminishes progressively after food. Now the same thing happens after exercise. The degrees of contractibility vary inversely to the amount of lymph effused. Exercise likewise provides [illegible] s to how tissue fluid is removed [illegible]. a short muscular contraction [illegible] two effusions, one during the contraction, which is entirely absorbed in 60 seconds, and another immediately afterwards, which disappears just as quickly, so that in four minutes we have two successive effusions which entirely clear up. The rapidity with which lymph disappears from the tissues in a state of rest favours the notion of absorption rather than that of transmission along the lymphatics. Now, experimentation on animals shows that muscular action of some kind is necessary to insure a flow of lymph along the lymphatics; so we may conclude that during exercise itself the muscular action will more particularly favour that passage for the lymph. If we admit the probability of these two routes being adopted—namely, the short circuit by absorption and the longer circuit by the lymphatics—we may gain some notion of the share which each takes in the removal of lymph from the tissues by resting one arm in a sling during exercise and immediately afterwards ascertaining the amount of lymph on the passive and on the active side. This I have repeatedly done, with the result that the finger on the passive side contains from 30 to 50 per cent. more lymph than that on the active side. Therefore, it is clear that the lymphatic route is largely adopted during exercise. It has been observed that the vaso-motor effects of exercise are hastened and increased by warmth and are delayed and diminished by cold. The effect of exercise on the digestive effusion of lymph is in the direction of increase inasmuch as during exercise a high level of lymph exudation is maintained.

Time fails me to touch on the practical bearing of the foregoing data on the importance of regularly maintaining the flushing effect of the fluid transfers between the blood and the tissue spaces, but I regret this the less as I cannot improve on the wise teaching of Sir Hermann Weber who so graphically and forcibly brought before us this aspect of the subject last December.[5]

FATIGUE.

Observation has shown that the rise in the arterial pressure produced during the continuance of exercise becomes less and less pronounced in proportion to the duration of the exercise; for example, the initial increase of from 15 to 20 millimetres of mercury gradually subsides until, after the lapse of a certain time (which varies with the tone of the individual and with the external temperature), the arterial pressure will not exceed 100 millimetres of mercury, and if the exercise is further continued, it will even fall lower, to 95, 90, or 85 millimetres of mercury. This point was also observed by Sir Lauder Brunton and Dr. Tunnicliffe who found that during a continuous series of leg movements (slow flexing of the legs on the thighs and the thighs on the trunk with shot-weighted ankles) extending over 30 minutes the arterial pressure rose during the first half of the time but fell to normal, or even below normal, during the second half.[6]

Why should the rise of pressure, normally induced by exercise, be effaced, or even be replaced by a fall, when exercised is prolonged? Inasmuch as the lymph exuded during exercise obstructs the contractile pressure of the muscular fibres on the intramuscular arteries and arterioles, the peripheral resistance caused by exercise will be reduced and the arterial pressure will gradually fall. In fatigue no amount of will exerted over the muscles can raise the arterial pressure at all; the muscles, though capable of ordinary contraction, become, as it were, lymph-logged. But massage quickly disperses the lymph and the contractibility is restored. Human instinct, without knowing the "why," practised what is now taught by physiological inquiry. We read in the Odyssey how the women rubbed and kneaded their weary heroes and thus invigorated them and we know that from time immemorial rubbing was the sovereign remedy for fatigue. Whilst doubting if massage can re-invigorate muscular fibres we admit that it can remove the lymph which obstructs their contraction and may thus produce a feeling of relief and restoration.

The physiology of fatigue includes another important factor—namely, diminished gravity control over the blood pressure. The outcome of exercise is the production of hypotonia in the vaso-motor mechanism, which is the central fact, as it were, of fatigue. You know, of course, that this condition implies the downward drain of blood through the toneless splanchnic arterioles into the capacious abdominal veins and the diminution of the blood-supply to the systemic and locomotive organs and to the brain. The splanchnic stasis is easily demonstrated in man. If a weight (e.g., a bag of shot, 14 pounds) is placed on the abdomen of a healthy subject, with normal arterial tone, that pressure will remain unaltered. Should, however, the arterial tone and pressure be reduced, the shot bag will raise it. This downward drain will doubtless raise the capillary pressure in the splanchnic area and thus increase the lymph flow from the abdominal organs; in a word, in fatigue the fluid transfer will become more splanchnic than systemic.

REST.

I have mentioned that during rest after exercise there is developed a steady and persistent rise of all the blood pressures (arterial, capillary, and venous) and a corresponding effusion of tissue lymph. Observation has shown that the volume and duration of this secondary outflow of lymph are always proportionate to the vaso-dilator or reducing effect of exercise and it is produced like the digestive exudation by cardiac stimulation. When it has subsided and the blood pressure has again become normal the tension test shows that the muscles have gained in contractility. Therefore the physiological intent of this lymph flow is to repair and to recharge the muscular fibres. How does nature thus automatically restore without the ingestion of food? In the first lecture I adduced some evidence to show that during digestion the important office of distributing pabulum to the tissues is relegated by nature to certain small quantities of waste products which, though themselves devoid of food value, accompany the food elements and by causing a reaction in the circulatory mechanism raise the capillary blood pressure and thus induce an exudation of lymph. Now we generate such materials in ourselves just as animals and plants create them for our benefit. Whenever we contract our muscles we initiate a series of chemical changes which produce such residua and the amount of these autogenous waste products will be proportionate to the duration and intensity of muscular action. There are two substances which produce, according to my observation, the characteristic double curve of arterial pressure induced by exercise and rest: these are creatin and ammonium lactate. It has been suspected that these substances form stages in the passage of proteid towards urea in muscle metabolism[7] and the physiological evidence I have obtained seems to me to support this view.

SLEEP.

According to my observations a large volume of lymph (not less than 20 per cent.) is exuded into the somatic tissues during sleep. The presence of this effusion is not only shown by the differential readings of the blood but is suggested by the tension test, for on first waking muscular tension, though strong, will not raise the arterial pressure more than a few millimetres if at all, whereas in five minutes or so it may elevate the pressure 40 or 50 millimetres. In sleep the arterial pressure falls very low (from 78 to 82 millimetres of mercury) and the venous pressure rises to a high point (from 40 to 50 millimetres of mercury) to a little over a half of the arterial pressure, whereas in the waking state it is only as a rule one-fifth of that pressure. The swollen state of the veins in sleep was recorded by Andreas Cæsalpinus over 300 years ago[8] and must have been the subject of observation even before that date (1593). In sleep there is complete vaso-motor relaxation, consequently the veins not only of the somatic but of the splanchnic area are filled with blood. The splanchnic stasis is shown by the fact that when the shot bag (14 pounds) is applied to the abdomen the arterial pressure is raised at once from 80 to 100 millimetres of mercury.

[8] Quæstiones Medicæ, 1593.

In a few minutes, however, when the subject is fully awake the arterial pressure rises to 95 millimetres of mercury or so, the venous pressure falls to 15 or 20 millimetres of mercury, the shot bag no longer raises the arterial pressure, and the effused lymph of sleep, having become absorbed, is no longer apparent. Mosso[9] demonstrated by his plethysmograph that during sleep the volume of the extremities increases and he naturally inferred that this fact was due to an accession of blood, though I think it may in part be ascribed also to the large exudation of lymph which irrigates the tissues during sleep.

What is nature's intent in thus supplying the tissues so liberally with lymph during our sleeping hours? The answer admits of no doubt—restoration—and how true to fact is the old proverb "He who sleeps dines." For during sleep nature provides the maximum amount of tissue lymph which we only obtain intermittently after meals. This fact suggests why sleep tends to plethora and obesity. Can the restorative power of sleep be demonstrated? The tension test furnishes the answer. I have for some time kept a night and morning record of the reading of muscle contractility, no tissue lymph being then apparent from the readings of the blood before and after compression, and I will here epitomise the results. In the morning before breakfast and after a good night the effect of muscular tension on the arterial pressure is nearly always greater than it is in the evening. This morning rise depends on the amount of exertion undergone during the previous day; when the day is spent quietly the rise may not exceed 10 or 15 millimetres of mercury but when much walking or cycling is done it may amount to 20 or even over 30 millimetres of mercury. The quality of the sleep is important, for if it be broken or much disturbed by dreams the morning rise is lessened. When in the morning I am in the best condition the tension rise will amount to 50 millimetres of mercury (half the normal pressure), when I am a little below par it will not exceed 35 or 40, and when slack it will not rise about 30 millimetres of mercury. This new application of the hæmodynamometer undoubtedly affords correct readings of the tone of the muscles. It suggests that the muscles are like accumulators, in that they are charged by every effusion of tissue lymph and are discharged by contraction and that certain physiological products, such as glycogen and adrenalin, are specially valuable in restoring contractility.

How does mere rest differ from sleep? During rest the vaso-motor mechanism is not relaxed as in sleep and lymph is then only exuded under the influence of lymph-pressor agents, whether exogenous (as during digestion) or endogenous (as after exercise). If there exist chemical causes for these lymph exudations may we not suspect that some product may be generated for the effusion during sleep? Retraction of the neurons is now the favoured theory of sleep, but if there be a chemical cause (perhaps, however, not probable) may it not be some substance which, relaxing the vaso-motor mechanism, raises the peripheral blood pressure and thus perfuses a large portion of the plasma into the tissues? Even after a meal the vaso-relaxant effect of sleep predominates and the blood pressure curves are vaso-dilatation, but on awaking they quickly resume the ordinary digestive form.

RESPIRATION OF GASES.

I have found that various gases and volatile bodies produce a marked effect on the blood pressure and lymph circulation. I have experimented with oxygen, carbonic acid, sulphurous acid, sulphuretted hydrogen, and a large number of volatile emanations. As I am at present prosecuting this part of the inquiry with Dr. Samuel Rideal, and as our results will appear later, I will confine my remarks to a general statement of the effects of oxygen, carbonic acid, sulphurous acid, sulphuretted hydrogen, and the atmosphere of sewers.

Oxygen.—When oxygen is inhaled for three minutes from Martindale's oxygenator the arterial pressure rises, for example, at once to 120 millimetres of mercury, and after ceasing to inhale the gas it remains at that height for fully five minutes, when it falls at the rate of one millimetre per minute, reaching 100 millimetres of mercury in 20 minutes, 80 millimetres of mercury in 40 minutes, and returning to normal in 20 minutes more. Two exudations of lymph of 20 per cent. each take place corresponding with two elevations of the venous pressure which indicate simultaneous augmentations of the capillary pressure. Oxygen differs from all other gases experimented with, in that its effects continue for some time after it has been inhaled (suggesting the initiation of chemical changes in the organism), whereas the effects of other gases cease at once. Besides this, the oxygen blood-pressure curves differ from those produced by any other product with which I have so far experimented.

Carbonic acid.—Having observed that the arterial pressure rises in a room with closed windows and doors in which a lamp or gas has been kept burning for some time, and will at once fall on opening a window or the door, I was led to make a number of observations with the blood-pressure gauge. This work has shown that the instrument affords a ready and practical test of the ventilation of rooms, workshops, places of public resort, railway carriages, &c. For example, while sitting in one of the "Tube" stations the other day I found my arterial pressure 125 millimetres of mercury, whereas before entering and on leaving the station it was 100 millimetres of mercury. Such an observation is easily made and the results obtained are definite. The observer selects a time when his arterial pressure registers 100 millimetres of mercury. He then enters the room or place to be tested; if the ventilation is bad the pressure at once rises 10, 15, 20, or even 30 millimetres of mercury, and if a window be opened or the observer retires from the room the pressure falls at once to the normal figure. There is a quantitative relation between the amount of carbonic acid and the increased pressure recorded. Carbonic acid shuts off tissue lymph like adrenalin (*vide seq.*).

Sulphurous acid, on the other hand, lowers the arterial pressure and when present in the atmosphere along with an excess of carbonic acid it checks or annuls the pressure rise of the latter.

Sulphuretted hydrogen.—When some of the Harrogate Old Sulphur Well water is poured into a basin and the emanations are inhaled the arterial pressure falls (e.g., in three minutes) from 100 to 90 millimetres of mercury and the venous pressure rises from 20 to 35 or 40 millimetres of mercury. This physiological effect is maintained so long as the sulphide gas is given off (an hour or more), and I am disposed to think that the element sulphur is the cause of it, for when this is taken at bedtime (as the compound sulphur tabloid of Sir Alfred Baring Garrod) the arterial pressure is lowered during the following day. Moreover, when half a pint of Harrogate water is swallowed the arterial pressure also falls, but when the sulphide is dissipated (the saline constituents only being left) the water raises that pressure (e.g., in 20 minutes) from 100 to 110 millimetres of mercury. I therefore conclude that the association of the sulphide with the salines is important in regard to the treatment of gouty states by the Harrogate sulphur waters.

The atmosphere of sewers affords some instructive facts in regard to the effect of gases on the blood pressure and the lymph circulation. I have made some preliminary observations on this subject. 12 men employed in the London sewers were selected—fine, healthy-looking fellows, as such men usually are. A shed about 15 yards from the entrance to the sewers was used, at noon, when the blood pressure is normal, for making the observations. Seven of the men had not been in the sewers that morning and their arterial pressure was 100 millimetres of mercury in every case. They were ordered merely to walk quietly about the sewers without working and after stated intervals to return, one at a time, every five minutes. The arterial pressure was found to have increased in every case, that of the first man (15 minutes in sewer) being 108, the second man (20 minutes) 110, and all the others 115 millimetres of mercury. Three men had been working in the sewers all the morning and in their cases the pressure was also 115 Two, without previous observation of the pressure, had been walking about in the sewers for half an hour and in them the pressure was also 115. All the men were ordered to walk about for 30 minutes in the open air after coming out of the sewers and in every case the arterial pressure was then found to be normal (100 millimetres of mercury). The whole of this evidence was consistent in showing that something in the atmosphere of the sewers caused the arterial pressure to rise. That rise was obviously not due to work, for the three workers had no higher pressure than the others, nor was it due to the heated atmosphere of the sewers, for heat lowers the arterial pressure. I do not think it was caused by carbonic acid, for the effect of this gas passes off almost instantaneously on leaving an ill-ventilated atmosphere. Whether the rise be due to marsh gas (methane) or to some other gas can only be settled by an analysis of the sewer atmosphere.

---

[9] Ueber den Kreislauf des Blutes im Menschlichen Gehirn. Leipsic, 1881.

In making these observations I gleaned a point of medical interest. Though these men who spend eight hours a day in the sewers are strong and healthy, they nevertheless, I am told, become in comparatively early life rheumatic or quasi gouty. The atmosphere of the sewers is apparently a stimulant of the circulation, for it raises the blood pressure, increases the pulse-rate very considerably, and flushes the skin; so that these men who spend a third part of their day in it have their tissues continuously charged with a large quantity of tissue lymph which signifies an excessive supply of pabulum for the maintenance of a high level of nutrition, the unknown emanation in the sewer atmosphere acting as their lymph factor. Hence, probably, the ultimate development of a chronic gouty disposition, just as with others, alcohol or an excess of meat may lead to the same goal. So even from the sewers we may gather a lesson in the pathogeny of gout.

INTERNAL SECRETION.

A doubt has been expressed as to whether the physiological effects of thyroid, suprarenal, and other extracts derived from ductless glands—effects established by experiments on animals—are demonstrable in man. That is a view which seems to me to be only accounted for by an unrecognised defect of technique, for ten years ago my first observations on the effects of suprarenal and thyroid were made on man and the results obtained prompted me to a conjoint inquiry with Professor Schafer which satisfactorily established them. Besides this, in the course of the present inquiry I have confirmed in man all the leading results which have been obtained by experimentation on animals with thyroid, suprarenal, pituitary, and testicular extracts. I purpose to do further work in this department and as time presses I will just now merely illustrate the effects of adrenalin and thyroid extract on the blood pressure and the lymph circulation. Fig. 7 shows the pressure curves and lymph exudation from a dose of adrenalin (one and a half tabloids hemisin = 0·00045 gramme adrenalin) and illustrates some of the leading conclusions of this inquiry. The powerful cardiac stimulant effect of adrenalin is indicated by the cardiometric rise of from 20 to 30 millimetres of mercury. As the arterial pressure rises and falls the cardiac excitation expresses itself in two elevations of the venous pressure (1 and 2) which indicate temporary rises in the capillary pressure producing modified exudations of lymph. These effusions, however, are soon absorbed by the rapid fall in capillary pressure (as shown by that of the venous pressure) produced by arteriolar contraction; and at the acme of the effect no lymph is found. An additional fact comes out in man. The rise in arterial pressure is followed invariably by a temporary fall, during which the capillary and venous pressures rise (3) and fresh lymph is exuded which is absorbed as the pressures become normal. The tension test confirms the absence of lymph at A B C and the limited effusions at D E F and shows a large net gain in contractility. You observe that the venous pressure throughout is (relatively to the arterial) reduced. By raising the dose the areas of lowered venous pressure and of the negative reading of lymph increase, and by reducing it the constricting action on the arterioles is subordinated to the cardio-stimulant effect and the capillary and venous pressures do not fall. May not nature adopt the latter course, using this wonderful molecule of adrenalin very sparingly? Should we not take the hint and prescribe it only in such small doses as half a hemisin tabloid (= $\frac{1}{430}$th part of a grain) in the tumbler of water with meals when we wish to secure its restorative effects as a lymph factor? This fact disposes me to think that adrenalin fundamentally

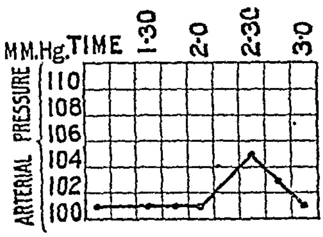
Effects of thyroid tabloid (five grains) on blood pressure and tissue lymph exudation.

* The word "arterial" is a misprint on the illustrative block for "venous."

stimulates the heart muscle more than the peripheral muscular fibres. Fig. 8 shows the effect of a tabloid of thyroid extract, five grains (Burroughs, Wellcome, and Co.), taken with an ordinary mixed meal. B is the lymph exudation produced by the meal without the tabloid and A with it. This limiting effect on the digestive lymph flow suggests why thyroid extract is often useful in reducing weight in obesity. In *Fig. 9* are recorded the arterial and venous pressure curves produced by thyroid extract. The cardiometric use of the pulse gauge shows that it is a cardiac depressant. Adrenal and thyroid extracts, taken together, neutralise each other's effects. In the example given in Fig. 10 the vaso-contraction of the adrenalin towards the end of the observation just overbalances the vaso-relaxant effect of the thyroid.

FIG. 10.



Purin- and salt-free meal, with hemisin (= 0 00045 adrenalin) and thyroid tabloid (five grains).

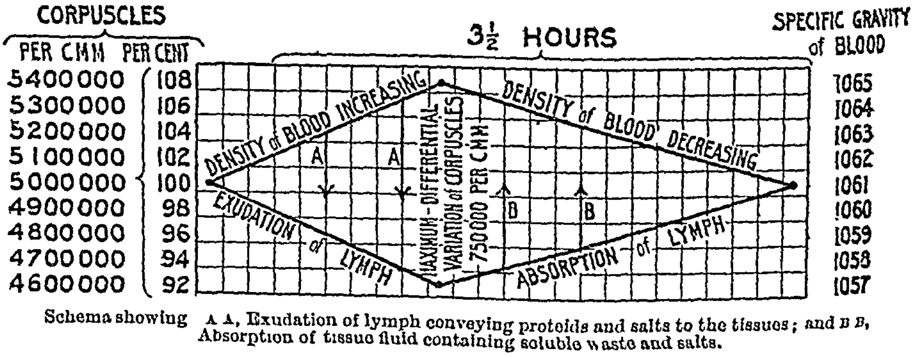
TEMPERATURE.

Warmth reduces vaso-motor and cardiac tone; it lowers the arterial pressure and the capillary and venous pressures rise. Its effects resemble those of sleep and thyroid. Cold increases vaso-motor and cardiac tone; it raises the arterial pressure and the capillary and venous pressures fall relatively to the arterial and then absolutely. It therefore acts on the lines of adrenalin. The amount of lymph is proportionate to the rise of capillary pressure.

GRAVITATION.

Is the lymph circulation, like the blood pressure, affected by gravity? If it were a certain amount of œdema would be normal and we know that this is not so. Although the toe does not lend itself to compression so satisfactorily as the finger I have succeeded in making several reliable observations which show that samples of blood derived from the toe before and after compression yield exactly the same differences as those furnished by the finger, proving thus that there is no such thing as physiological œdema.[10] How is this? It is obvious that we must take into consideration some other factor in lymph production besides the blood pressure. Professor E. H. Starling of University College has shown that that factor is the difference of permeability in the capillary wall. He has demonstrated that the permeability of the capillaries of the liver and intestines is much greater than that of the limbs, and of the former the hepatic capillaries are more permeable than the intestinal. In like manner my observations suggest that there is a difference between the permeability of different districts of the systemic capillary area, so that the effect of the blood pressure on the lymph flow is made uniform by differences in the permeability of the capillary wall.

FIG. 11.



Schema showing A A, Exudation of lymph conveying proteids and salts to the tissues; and B B, Absorption of tissue fluid containing soluble waste and salts.

IS TISSUE LYMPH A SECRETION OR AN EXUDATION?

Many physiologists believe that lymph is a secretion product and I should like to refer you to a *résumé* in favour of that view in the recently issued excellent translation of the work of Poirier, Ciméo, and Delamere on the lymphatics by Mr. Cecil Leaf. On the other hand, the old pressure theory of Ludwig still survives and no one has done more valuable work in support of it than Professor Starling whose results,[11] with those of Baylis,[12] Lazarus-Barlow,[12] Leathe,[12] and Tubby,[12] should be thoroughly studied by every one who aspires to a sound view on this question. All my observations support the conclusion that tissue lymph is a filtrate or pressure product. But I can fancy someone asking, "Is not the digestive lymph effusion, concurring as it does with the flow of gastric juice, an evidence of the secretion theory?" I will therefore try to answer this question.

Pawlow has shown most clearly in his experiments on sham feeding in œsophagotomised dogs that the secretory activity of the gastric glands mainly and primarily depends on the psychical influence of appetite, and that contact between the food and the stomach wall only indirectly brings that activity into play by awakening or increasing a desire for food. Now, all my observations on the digestive lymph differences clearly show that the rôle of the psychical element is subordinated to that of the ingestion of food, for I have never found that an appetite, with food in sight, is of itself sufficient to cause the slightest flow of lymph. Moreover, my observations clearly indicate that the only substances which excite that flow are those food elements and foodstuffs containing them which raise the capillary blood pressure, whether these materials be pleasant to the palate or otherwise. Furthermore, many investigators have injected strong meat extracts per rectum into animals without detecting the least sign of gastric gland activity,[13] whereas I have found that rectal injections in man of beef extracts and of other physiological products which raise the blood pressure cause the same flow of tissue lymph as when the extractives are swallowed. From this fact we may conclude that the chemical excitants of the gastric glands act, as Pawlow believes, on the peripheral afferent nerve endings in the stomach and thus reflexly stimulate the glands; and that, on the other hand, the active principles which produce the lymph flow must first be absorbed into the blood so as to raise the blood pressure before they can create that flow. I think that this position is of practical interest in showing how rectal feeding may nourish the body by inducing a flow of tissue lymph, even though gastric digestion be for the time in complete abeyance. We may therefore conclude that though these two events (the gastric secretion and the lymph effusion) are associated when digestion is going on they are nevertheless distinct processes, one being a secretion primarily under psychical control, though amenable to special stimuli acting on the gastric nerve centres; and the other an outflow into the interstitial spaces induced, not only by digestion, but by exercise, sleep, or any of the physiological products submitted to observation in this inquiry.

IS THERE AN INTERMEDIARY CIRCULATION?

The rapid removal of lymph from the tissues when the muscles are at rest, for example, after exercise and on awaking from sleep, suggests absorption rather than transmission by the lymphatics. Therefore, I think, there is evidence in support of a circulation of fluid independent of the lymphatic circulation, though controlled by the capillary circulation, of which it may be said to be an extension.

There is not time to discuss the forces involved. The best account of them as at present known is that given by

---

[10] At one time I thought that physiological œdema was not improbable. See Croonian Lectures, 1896.

[11] Text-book of Physiology, by Professor Schafer, F.R.S., &c., vol. I.

[12] Journal of Physiology (Cambridge and London), vols. xvi. and xix.

[13] Pawlow: Op. cit., p. 103.

Professor Starling.[14] Ludwig pointed out that the prime factors in the effusion of lymph are filtration and diffusion. My observations refer only to filtration and they a[illegible] such a schema of the intermediary circulation as is [illegible] sented in Fig. 11, which shows the mechanism, [illegible] were, for the supply of pabulum to the tissues (A A) and for the removal of soluble waste from them (B B). The view there represented explains why the ingestion of food restores the tissues at once and long before the food itself can be assimilated into the blood. The exhausted tissues have not, therefore, to remain unsupplied until the food becomes part of the common store of pabulum which the blood keeps ready for distribution. Each supply of food may be viewed as a deposit paid to our banking account; but it is not merely a deposit, for nature combines with it a cheque for payment; the banker, therefore, is compelled to reimburse at the same time that he receives, so that the balance is kept fairly uniform. But nowadays in our strenuous preoccupation we too often rely solely on the seductive cheque, forgetting the necessary deposit, and so living on the blood itself the balance dwindles.

In normal subjects each effusion of tissue lymph is intermittent, rising out of, and subsiding into, an apparently lymph-free state of the tissues when the capillary blood pressure (as indicated by the venous pressure) touches its minimum point. Probably at such times some trace of tissue fluid is actually present but insufficient to be made apparent by the ordinary use of the differential test. Extended observation has demonstrated that this intermittent discharge and absorption of tissue lymph become remittent in a large number of cases in which the capillary blood pressure is persistently raised; when, in fact, the intermediary circulation is thrown out of gear.

SOME PRACTICAL DEDUCTIONS.

I am fain to hope that this inquiry enables us to recognise some order in the normal reactions of the blood pressure and lymph circulation to the leading physiological conditions, and that it provides us with a somewhat clearer notion when the normal blood pressure can be relied on as a good base line remaining uniform for experimental and comparative clinical determination. Extended observation has shown that at such times the blood pressure is much more uniform than is usually supposed, and that disregarding physiological variation greatly impairs the precision and accuracy of the clinical determination of it. In the ordinary course of work, where observation cannot be made at the most reliable time (within an hour before a meal), I have found the following rule useful as a correction to the disturbing effect of digestion on the arterial pressure: to deduct from a pressure observed in the first hour 15 millimetres of mercury, in the second hour ten millimetres of mercury, and in the third hour five millimetres of mercury.

Clinical work has shown that we meet with two great departures from the normal condition of the circulation—one in which there is a hypotonic and the other a hypertonic state of the vaso-motor mechanism. The former is characterised by splanchnic stasis, which, in the active postures of the body, diminishes the systemic blood pressure and the flow of tissue lymph dependent on it. You know, of course, that as physicians we speak of the blood pressure as synonymous with the arterial pressure, for this pressure is the most important from the clinical standpoint; but the capillary is the working physiological blood pressure, for the arteries and the veins are but conduits for the passage of the blood to and from the seat of the metabolic traffic—the capillaries. Now this functioning pressure in the systemic districts of the body is lowered (relatively to the arterial pressure or absolutely) in all hypotonic states and the obvious indication is to raise it, as by the ingestion of those foodstuffs richly endowed with lymph factors and to guard against further splanchnic vaso-dilatation by limiting exercise and prolonging the intervals of rest.

The hypertonic state of the circulation is found in many acute and chronic ailments. When persistent it includes [illegible]es, some (such as chronic [illegible]) the outcome of organic [illegible] the product of toxæmia. The last section embraces the majority of cases belonging to that large class of ailments which we call gout, a term regarded by some as a convenient label for a sort of rubbish-heap of nondescript ailments. Having, however, devoted many years to the study of the circulatory facts presented by gouty subjects (some hypotonic but the majority hypertonic), I am satisfied that we have in these facts faithful indications of the operation of a common cause which links these cases together; chronic goutiness has, therefore, grown more and more real to me as inquiry proceeded. There is not time to discuss the causation of gout, but I should like to ask you to imagine what would happen to the normal alternations of the circulation of blood and lymph which I have described were the digestive exudations made to overlap by an excess of the exogenous lymph factors. Would not the blood pressure gradually rise until at last the intermittent subsidences to normal before each meal ceased to recur; and would not consequently the absorption of tissue fluid be checked and the tissues become continuously charged with it? This is, indeed, the position which has been demonstrated by ample clinical observation (Fig. 12, B). In the hypotonic states (e.g., neurasthenia, phthisis, &c.) the effusions of tissue lymph are diminished (Fig. 12, C). Hence the value of forced feeding, and especially meat feeding, which charges the tissues highly with lymph, as in goutiness. Many clinicians (Dr. J. E. Pollock, Sir Dyce Duckworth, Sir Hermann Weber, and Dr. F. Parkes Weber[15]) believe that gout is antagonistic to phthisis. For long I have held that view.

This inquiry, I think, affords a few suggestions on the dietary of gout, with the view of controlling and limiting the excess of exogenous lymph factors. This excess, we must remember, will be determined by the eliminative power of the individual and by the activity of his endogenous production of lymph factors. Dr. I. Walker Hall[16] has published estimations of the purins contained in the various meats which he has analysed and I calculate from his data the following averages: for white meats or fish (rabbit, veal, chicken, turkey, cod, plaice, and halibut), 0·1012; for mutton, 0·1025; and for beef, 0·1502. So it seems that we are wise in preferring mutton to beef, but I doubt if we gain much by selecting roast white meats only. Boiling the meat and excluding the broth are far more effectual in limiting the digestive lymph wave than taking roast white meats, and in this way even beef may be made less harmful for the gouty than roast chicken or fried white fish. Patients will often say, "I have faithfully carried out my doctor's orders. I have lived on white meats, never touching beef or mutton, and here I am as gouty as ever. Is

[14] Schäfer's Text-book of Physiology, vol. i.

[15] Remarks on the Relations of Pulmonary Tuberculosis to other Diseases by F. Parkes Weber, M.D., F.R.C.P., THE LANCET, April 2nd, 1904, p. 924.

[16] The Purin Bodies of Foodstuffs and the Rôle of Uric Acid in Health and Disease, by I. Walker Hall, M.D., pp. 39-49.

it not clear that diet does not control gout?" One then goes into particulars and soon finds an explanation of the enigma. It is discovered that the proportion of the foodstuffs more highly charged with purin bodies, as compared with those containing smaller quantities of these bodies, has not only not been reduced but has actually been increased, this result having been attained by withdrawing the carbohydrate foodstuffs, such as potatoes, rice, tapioca, fruits, and sugar, which (except perhaps sweet fruits containing lævulose) have yet to be proved to be injurious in the gouty state. Dr. Walker Hall shows[17] that the following are free from purins: eggs, white bread, rice, tapioca, and green vegetables (cabbage, lettuce, cauliflower), and that potatoes, butter, and cheese are practically free. These are all valuable constituents of the somewhat limited dietary of gout, and I have moreover proved that they cause no reaction in the circulation. On the other hand, gravies and the meat extracts (so frequently used in cooking) produce large exudations and should be prohibited or should be greatly limited.

My experience shows that an excess of sodium chloride makes all forms of dietary in gout futile. I have often been struck with the great liking for salt which gouty subjects develop, especially when over 60 years of age, and as often have I been gratified by the favourable results obtained by prohibiting unboiled salt meats and limiting the supply of salt, or combining it with potassium chloride, or substituting potassium chloride for it. I have found that all alcoholic beverages (except gin) increase the amplitude and duration of the digestive lymph waves—brandy, wines, and malt liquors being the most active of these lymph-pressor agents. This greater activity is apparently due to alcohol and its congeners and not so much to the purins—for wines are free from these bodies, and lager beer, pale ale, and porter do not contain very much of them.[18] Whisky is much less lymph pressor, and gin when taken with food actually reduces the lymph exudation (e.g., from 20 per cent. to 12 per cent.) and should therefore prove useful in most forms of hypertonia.[19] The methyl purins of tea, coffee, and cocoa, so valuable in health, probably play their part in increasing the continuous charge of tissue lymph in gout; but I think they are much less active than alcohol and its congeners in spirits, wines, and malt liquors.

According to my experience, when in a case of gout the diet has been properly adjusted the normal intermissions in the tissue lymph circulation are restored; there is then no longer need for further restrictions and it is rarely necessary to make the dietary irksome—if only the rules imposed are faithfully observed.

NEW REMEDIES SUGGESTED BY THIS INQUIRY.

This inquiry has suggested the use of some of the organic products I have experimented with as remedies. Though I have only so employed them in a tentative way the results encourage me to prescribe them and perhaps others may also like to do so. They are all prepared as tabloids by Messrs. Burroughs, Wellcome, and Co. Two are vaso-dilators—ammonium hippurate and lichenin; the last body is a polysaccharide obtained from Iceland moss and certain algæ, and must be a sugar of a remarkable chemical constitution. After the immediate effects of a dose (two grains) of the hippurate, lasting about an hour, have passed away, the vaso-motor mechanism is impressed by it for fully 24 hours; in normal subjects the arterial pressure during that time falling five millimetres with a corresponding rise in the venous pressure. Witte's peptone is the only other agent I know which produces a similar lasting effect on the circulation. So far I have prescribed the hippurate only once a day, and the results in reducing the arterial pressure and in improving the general health and well-being have been excellent.

The other products, glycogen and lævulose, exert a contrary effect. Glycogen is made up in one-grain tabloids. At present it is somewhat expensive but its physiological effect is so decided as a vaso-tonic and renovator of muscular contractility that I anticipate it will prove a useful restorative in hypotonic conditions (neurasthenia, phthisis, &c.). The saccharide lævulose is also promising in the same direction. Hugo Weber[20] last year published some striking curative results in the treatment of phthisis in which lævulose produced a very pronounced gain in weight. It is made up in ten-grain tabloids, of which two or three can be taken with food.

I have also made observations (physiological and clinical) on the effect of Witte's peptone. Knowing the work that has been done showing the backward conversion of peptone by the alimentary mucosa I did not expect to find any alteration of the blood pressure from the ingestion of this product. Though observation contradicts this anticipation I do not, however, think that the results are due to peptone at all, for they are not produced by commercial peptone. I suspect that they arise from the presence of amido acids, for I find that leucine and tyrosine, and especially leucine, are much more active vaso-dilators than Witte's peptone. Moreover, these ultimate products of proteid cleavage would not be intercepted or transformed by the gastric mucosa.

The physiological action of peptones and proteoses on the vaso-motor system and the urine has been well worked out by Professor W. H. Thompson.[21] Witte's peptone contains very active constituents and the tabloids which I have used are in grades of one-quarter, one half, and one grain. No disturbing effects of any kind have been observed to follow the one grain dose, but as the effect on the vaso-motor mechanism seems rather to increase than to diminish with the continuance of the remedy smaller doses suffice to maintain it. Hitherto I have prescribed it only once a day and when the arterial pressure tends to fall to 100 millimetres of mercury I have given it every other day or substituted a smaller dose of it or of ammonium hippurate for continuance. In one case the arterial pressure which was 148 millimetres of mercury (and had been for some years from 140 to 150 millimetres of mercury) gradually subsided under the daily dose and at the end of a week it was normal, and remained normal with the same dose three times a week. The improvement in the patient's general health was marked. I have obtained similar results with half a grain and even quarter of a grain doses in cases in which the rise of the arterial pressure was somewhat less than this. I am hoping that we may find in this substance or in ammonium hippurate or in the amido acids a long-felt clinical want supplied—namely, a remedy possessing a vaso-dilator action less fleeting than that of the nitrites which are so valuable for emergencies.

Want of time prevents me from bringing before you several other branches of this subject, such as the effects of tobacco smoking, of the important physiological products choline and neurin, and of various drugs on the tissue-lymph circulation. Moreover, I have been unable to touch on the obvious bearing of this study on our knowledge of œdema simple and inflammatory. There is much more work to be done, but meanwhile let me briefly summarise a few provisional conclusions.

1. Tissue lymph is intermittently effused, for example, after the ingestion of food, during exercise, rest after exercise, and during sleep.
2. The rapid effusion and removal of it in states of rest suggest the probability of a circulation between the blood and the tissue spaces—a circulation independent of the lymphatic circulation.
3. The apparent physiological intent of the effusion is reparative and that of its absorption is the removal of tissue waste.
4. The normal intermittency of the fluid exchange becomes in many pathological conditions less and less complete.
5. By studying the conditions which increase or decrease lymph effusion we ought to gain a clearer insight how to control derangements of nutrition and metabolism.

CORRIGENDA.—In Lecture I., p. 1176, first column, ninth line from top, read "between two pressures higher than the normal capillary pressure." P. 1177, second column, twenty-sixth line from top, read "very often go together."

CROWNHILL CONVALESCENT HOME.—The annual meeting of the subscribers to the Crownhill Convalescent Home, near Plymouth, was held on April 29th under the presidency of Mr. W. Bastard. The report stated that 268 patients had been admitted during 1903. The financial statement showed that there was an adverse balance of £29. The home has now been established 20 years. Sir Massey Lopes has recently given £500 towards the endowment of the institution.

ABNORMAL MUSCULAR CONTRACTIONS.[1]

BY E. NOBLE SMITH, F.R.C.S. EDIN.,
SENIOR SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL, LONDON.

I DO not propose to trouble you with a dissertation on the whole pathology of abnormal muscular contractions but I would introduce my subject by referring to the various heads under which these contractions may be ranged. We may divide the whole subject into two classes of causes: (1) causes originating in the nervous system; and (2) causes originating in the muscles themselves. In the first class we may make the following divisions:—A. Conditions inducing active spasms of muscles. These may be congenital or acquired. Of the acquired class we have: (*a*) permanent spasm resulting from disease of the brain (as in the "late rigidity" of hemiplegia); (*b*) permanent spasm arising from disease of the spinal cord (as in spastic paraplegia or as in lateral sclerosis, or temporarily and of a spurious character, as in Pott's disease); (*c*) permanent spasm due to lesions of the trunks of nerves (as sometimes occurs after facial paralysis); (*d*) hysterical spasm (spastic club-foot may occur); (*e*) tetanic contraction; (*f*) permanent spasm arising from reflex causes; and (*g*) permanent tonic spasm arising from causes of nervous origin but not included in the above (as in spasmodic torticollis). B. Conditions leading to passive contraction of muscles without spasm. These also may be congenital or acquired. To the former it is supposed by some that ordinary club-foot belongs, although it is quite possible that these congenital cases may have commenced as spasmodic nerve contractions. Of the latter we have (*a*) those cases due to unbalanced action of groups of muscles where the antagonistic groups are paralysed (as in infantile paralysis); and (*b*) those due to the maintenance of a paralysed limb in a shortened position for a considerable time by spasm (this is the most frequent condition in acquired club-foot). I will now deal briefly with the several examples which I have referred to in the foregoing outline of causes.

Pott's disease.—It will probably suffice if I quote the remarks which I have made upon this subject on p. 28 of my small work "Paralytic Deformities of the Lower Extremities": "Spastic contraction of the flexors of the lower extremities in patients affected with caries of the spine denotes an extension of inflammatory mischief, pressure upon the spinal cord and consequent myelitis. However severe the contraction may be, tenotomy is inappropriate so long as spasm, denoting an active condition of caries, remains. Pressure on the cord from an abscess may sometimes necessitate the performance of laminectomy, but as a rule the spasmodic contractions resulting will subside under efficient fixation and general treatment. When, however, the active caries has been subdued and consolidation of the bones has taken place, then, if permanent contracture remains, it will be necessary to perform tenotomy, particularly of the tendines Achillis."

Hysterical spasm.—It would be difficult to define the nature of hysterical spasm. When one part of the body, such as a foot, is held constantly and rigidly in one controlled position I doubt very much if hysteria will altogether account for the distortion. One of the most markedly hysterical young women I ever saw was sent to me with severe talipes equinus for operation. I recognised this as a hysterical case and declined to operate. I treated her by the Weir-Mitchell system, the foot receiving particular attention from the masseuse. At the end of six weeks the patient was greatly improved as regarded her general condition and the spasm of the foot had relaxed, but there was then revealed a permanent shortening of the calf muscles causing a certain degree of contraction of the foot, but nothing like the amount which had formerly existed. I then divided the tendo Achillis and restored the part to a normal condition and there was no more trouble with the foot. In hysteria we more often find an exaggeration of symptoms, perhaps a gross exaggeration, than a mere simulation. In other words, there is generally some reality underlying the neurotic element.

Spasmodic torticollis.—This affection is characterised by almost constant spasmodic action of the sterno mastoid of one side only. In a few cases the muscles on both sides are affected. When these spasms have continued for many months or years the posterior cervical muscles, especially the splenius capitis, also become involved in the morbid action. This happens on the other side to that of the acting sterno-mastoid. There are other varieties which I have described in my pamphlet upon this subject.[2] In that publication I showed that treatment by drugs had always failed to cure the affection and I therefore advocated operation. Campbell de Morgan of Middlesex Hospital in 1866 divided the spinal accessory nerve and cured a severe case, but no other surgeon so far as I know had since then repeated the operation until I resuscitated this treatment. In 1880 I wrote a letter[3] recommending this procedure. On April 22nd, 1890, having previously stretched the nerve, I operated on my first case. I first published a statement of this case in April, 1891.[4] In this case I subsequently (May 28th, 1890) excised pieces from the external branches of the posterior divisions of the second, third, and fourth cervical nerves and cured the patient. At this time there was no record of operation upon the posterior cervical nerves having been carried out and if my paper had been published when it was received it would have been the first published case. The pressure on the space of the journal in consequence of Koch's discoveries regarding his treatment of tuberculosis delayed the publication of my paper for six months and just before it appeared Keen of America reported a similar operation performed by himself. I have operated 16 times and in every case a satisfactory result has taken place In several instances (and it may be in all) the nerve has reunited after a certain period from six months onwards and the function of the sterno-mastoid has been restored without any return of the spasm. Not only have the spasms been removed by these operations but there has been no permanent weakness produced by the paralysis of one sterno-mastoid and no deformity has resulted from the loss of action of this one muscle, although the contrary has been stated upon theoretical grounds as being sure to result. There can be no doubt that the other numerous muscles of the neck keep the head straight.

Congenital and acquired club-foot.—It will doubtless serve the purpose of this paper if we discuss the treatment of congenital talipes varus or equino-varus only, this form of club-foot being the most common and characteristic of all. The treatment of club-foot in the past—I mean subsequently to the introduction of tenotomy and before the time of osteotomy—consisted in continued pressure by means of splints and surgical boots and the division of resistant tendons and fasciæ. This procedure was very slow and tedious to both patient and surgeon. One very important detail of the method was to defer operation on the tendo Achillis until the varus part of the deformity (the turning in of the front part of the foot) had been thoroughly overcome and this procedure continued to be of the greatest importance. The fixation of the heel in a contracted position caused by shortening of the calf muscles gives the surgeon great leverage power in his endeavours to draw the forepart of the foot into a straight position. When this varus deformity had been entirely overcome the equinus which remained was easily removed by division of the tendo Achillis and careful after-adjustment to insure a correct lengthening of the tendon. The treatment as thus briefly sketched occupied nearly the whole period of growth, for although the more active interference took from three to six or eight months the patient had to be under occasional observation for several or many years and would probably during that period have to wear some kind of retentive apparatus.

Osteotomy.—Upon the introduction of osteotomy it was thought that a solution of the difficulties and the removal of the tediousness of the previous treatment of club-foot had been discovered. The removal of a wedge of bone or the ablation of separate bones from the tarsus and the immediate placing of the foot in a comparatively straight position, it was [illegible] ire. It was said to be [illegible] it really seems to be, [illegible] tly removed the struc- [illegible], in fact, is a mutilation of the foot and the joints become more or less ankylosed and useless. The patient may be able to place his foot or what remains of it flat upon the ground, but he loses that exquisite elasticity with which nature has endowed this human member. I have seen a great number of cases exhibited at various societies as examples of the success of osteotomy but I have always considered them examples of the failure of that operation. The patients have moved about with what we may call stumps instead of natural feet.

[1] A paper read before the Chelsea Clinical Society on Feb. 16th, 1904.

[2] Spasmodic Wry [illegible]

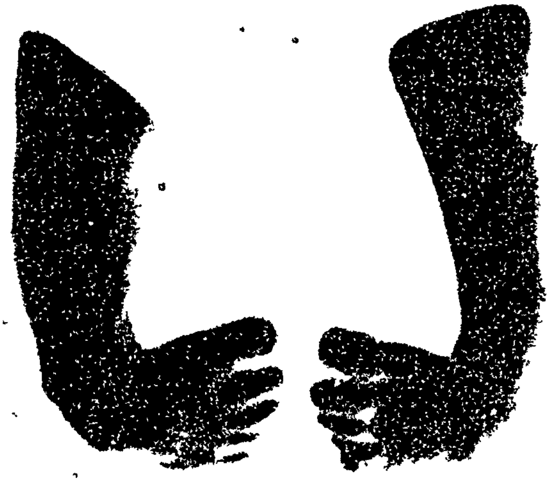
Another operation advocated for this deformity is subcutaneous division of all the soft tissues on the inner side of the sole down to the bones (Buchanan's operation). Regarding this procedure I may quote the late Mr. W. J. Walsham, whose opinion I think was always sound and unbiased. He adopted this procedure in a few cases and he states: "At the time of the operation the shape of the foot was certainly much improved and no apparent harm followed the division of the nerve and artery. We were disappointed, however, with the result, and in one case had subsequently to remove the astragalus." Then, again, we have subcutaneous division of all the soft tissues in the sole of the foot and behind the internal malleolus. I again quote Mr. Walsham who wrote: "This operation does not commend itself to us. The severance of the whole of the arteries, nerves, muscles, fasciæ, and ligaments in the sole of the foot, as well as the whole of the soft parts behind the inner ankle, together with the tendo Achillis and posterior ligament of the ankle, appears to us a very severe and, we are tempted to say, not a very scientific procedure." With the opinion thus expressed by Mr. Walsham I entirely agree.

Another operation which has received much attention is the open incision of all the soft tissues on the inner side of the foot down to the bone (Phelps's operation). The late Dr. A. M. Phelps of New York devised and brought this operation before the medical profession in 1881, since which time it has been largely adopted by general surgeons in this country. At the annual meeting of the British Medical Association at Ipswich in 1900 Dr. Phelps was present and advocated his method of operating. At that meeting I, as well as other surgeons connected with our London orthopædic hospitals, expressed an opinion adverse to Dr. Phelps's operation for the following reasons. That any improvement that may be effected in the position of the foot at the time of operation will have a tendency to relapse as the parts heal and contract. Just as in the case of severe burns accompanied by great loss of tissue the gap made will recontract unless a plastic operation is performed to fill up the parts which are wanting, so in Phelps's operation the contracted part being divided and separated must close together again. In a contraction from a burn if we cut through the cicatrix and separate the parts, however much we may try to keep them asunder the healing process will reproduce the deformity.

Professor A. Ogston of Aberdeen has devised a much better procedure than osteotomy or the other severe cutting operations which I have referred to. In the case of children in whom the tarsal bones are chiefly cartilaginous this surgeon cuts into the bones separately and scoops out each osseous centre until sufficient is taken away to enable the deformity to be entirely corrected by manipulation. The joints are left intact.

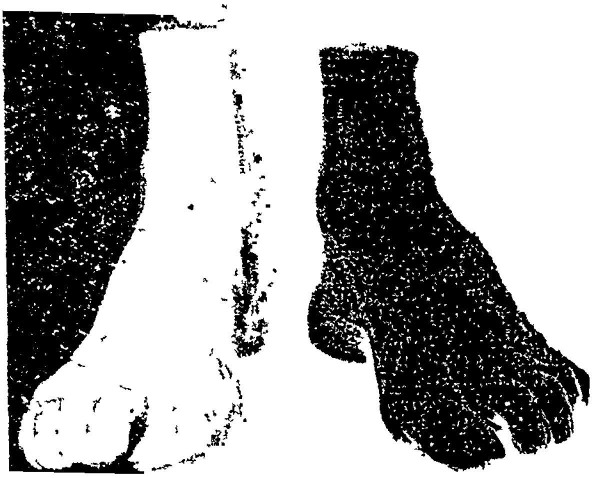
Rapid reduction by moulding.—I will now describe the plan of dealing with club-foot which I think is superior in every way to all other procedures yet described. I must first state that the treatment by manipulation, which I mentioned as being so successful, and the subsequent use of apparatus to keep up the good position until the bones have grown to their natural shape, occupies a considerable length of time—for instance, the case that I exhibited at Ipswich and of which I now give illustrations (Case 1, Figs. 1 and 2) occupied three years in producing the effect shown in Fig. 2. This even did not suffice and it was considered desirable that the boy should continue using a very simple light instrument for several years longer. This treatment is tedious but not so troublesome as may be thought. The principal part is accomplished in the first six months and after that the patient is only seen perhaps at intervals of three or four months. After the age of three years the patient referred to was only seen by me about once a year, until at the age of 15 years the feet were absolutely normal in every respect. In comparing this procedure with Phelps's operation and also with osteotomy we find that even with these heroic methods mechanical support has to be kept up almost if not quite as long as I have indicated even to produce a partial improvement. Now the procedure which I am about to describe is a modification of the treatment by manipulations and immediate reduction after tenotomy which I had practised for a number of years. The modification which I now employ was introduced to my notice by Professor Lorenz of Vienna. As a result of this modification the varus part of the deformity may, in many cases, be overcome at one sitting. Others may take two or more operations at intervals of a few weeks. In every case the foot is put up in a plaster-of-Paris casing, with due precautions against undue pressure, and kept up for some months.

Fig. 1.



Case 1. Cast taken shortly after birth, December, 1884.

Fig. 2.



Case 1. Cast taken at the age of 15½ years.

The reduction of club-foot by forcible manipulations is, as I have said, a very old procedure but there is a vast difference in the details of carrying it out. As regards Lorenz's method I have during the past year obtained far better results by this plan than I ever did before. Some surgeons advocate the use of mechanical wrenches and possibly for those operators who do not possess much muscular strength such a method may be necessary, but I am inclined to think that these manipulations are done better with the hands alone. By the latter means we retain more thoroughly the sense of touch, a feeling of give and take which is deficient in using the mechanical wrench. It is not absolute violence which leads to success; it is the steady, persevering, unremitting pressure, constantly varied from one point of bearing to another, which produces the best results Feet which during the first five or ten minutes' working seem hardly to give way at all gradually succumb to the continuous though varied pressure. In former days I used to persevere for perhaps five or ten minutes in trying to correct a foot and then placed it in the best position which could be maintained in plaster of Paris bandages Now I persist for half an hour, three quarters of an hour, or even longer Gradually the parts become lax and softened and one is able to manipulate the foot into any shape one likes It is, of course, tremendously hard work, and the more careful one is to avoid damage, such as deep bruising, the harder the work is

FIG 3

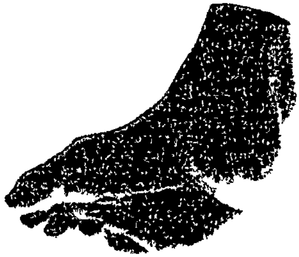
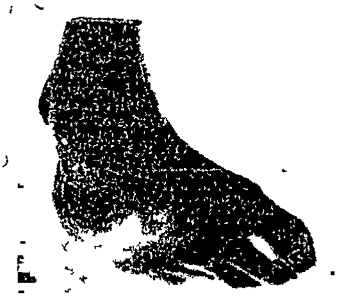
FIG 4



Case 3, aged 12 years Cast of right foot posterior view, taken before operation, February, 1903

FIG 5

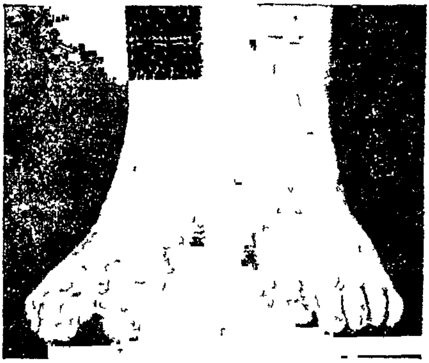


Case 3 aged 12 years Cast of right foot, anterior view taken before operation, February, 1903.

CASE 2 —On March 13th, 1903, I tried Lorenz's treatment in a woman, aged 40 years, suffering from congenital talipes varus, and who walked on the sides of her feet. She had been treated from childhood by several surgeons At the first operation a great deal of the deformity was overcome but having worked as hard as I could for an hour I did not feel equal to do any more, besides I doubt if it would have been judicious to continue the "sitting" The foot was maintained in its improved position by plaster of Paris bandages At the second operation on May 20th, nearly ten weeks after the first, I succeeded in overcoming entirely the varus position Again the feet were secured in plaster of Paris bandages There remained, however, some contraction of the calf muscles and contraction of the toes Therefore on Oct 6th last I divided the tendo Achillis of both feet and the extensors of all the toes This was nearly seven months after the first operation On Dec 28th, 1903 she was able to walk a *mile comfortably* and was *improving daily* She can now walk barefooted with her feet flat on the ground, but she will naturally have to wear light supports for a time

CASE 3 —A male patient, aged 12 years, was admitted to the City Orthopædic Hospital in February, 1903 His feet appeared as shown in Figs 3, 4 and 5 The first operation was performed on Feb 20th, 1903, the second on March 31st, the third on June 3rd, the fourth on July 21st, the fifth on Oct 7th, the sixth on Nov 11th, the seventh on Dec 11th and the eighth on Jan 1st, 1904 The feet now appear as in Fig 6, as shown by plaster casts and the boy can walk without any artificial supports with his feet flat on the ground There is still a slight shortening of the calf muscles which will require section of the tendo Achillis to make an absolutely perfect result, but such result is now certain

FIG 6



Case 3 aged 13 years Cast of feet anterior view each patella facing directly forwards Taken February 1904 one year after first operation

As to the exact changes which take place and allow the foot to be corrected I hesitate to give an opinion. In young children there can be little doubt that the cartilaginous bones become softened and can then be remedied, but in an adult, such as I have just described, the altered position must be chiefly or entirely due to giving way of the restraining ligaments and fasciæ. I must own I was surprised that the feet in the case of the woman aged 40 years should have become firm in so short a time and able to bear the weight of her body In the application of the plaster bandages after reducing the deformity the foot and the lower two thirds of the leg must first be covered cotton-wool bandage as thick as possible consistent with free control of the foot when applying the plaster bandage. Then the wool must be kept in place with a linen roller bandage and over that the plaster-of-Paris bandage is placed. If there is any doubt about the freedom of the circulation a window should be cut through all the bandages over the instep. This window will not only relieve undue pressure but will also enable us to watch the skin at the point where the greatest pressure has been made and to treat any superficial abrasion that may have been produced by the process of reduction. There is generally some pain for the first 12 hours after operation, but if it continues after that period then the window should be enlarged or part of the bandage or the whole must be removed and reapplied. The greatest care must be observed so as not to do damage by an over-tight plaster bandage.

Causes originating in the muscles themselves.—We have one more class of cases to consider, that is, the contraction of muscles from traumatic injury. Time will not allow me to enter fully into this subject. I will merely remark that I have met a considerable number of cases where isolated contractions have been found in various parts of the body, following a blow or some strain of the part. Many of these cases have existed for a number of years and have been treated by massage, electricity, baths, stretching, actual cautery, and blistering, all of which have failed to produce the slightest benefit, whereas subcutaneous section of the contracted muscles has immediately removed the pain and the difficulties of movement. I will give one instance of this. A boy, aged 14 years, was suffering from one of those contractions at the bend of the elbow. It did not interfere with the ordinary movements of his arm but prevented him from bowling at cricket. Being a very good bowler his parents were anxious he should not be further incapacitated from this acquisition. The tight fibres could be felt in front of the internal condyle of the humerus extending upwards, probably the border of the brachialis anticus. These fibres I divided subcutaneously and the difficulty was removed. This was probably the sort of case which bone-setters sometimes cure by violent wrenching.

Queen Anne-street, W.

MESENTERIC CYSTS.

BY E. P. BAUMANN, M.D. EDIN., M.R.C.P. LOND.,
MEDICAL REGISTRAR AND PATHOLOGIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

ISOLATED cases of mesenteric cysts had been described as early as the seventeenth and eighteenth centuries, but it was not until the latter half of the nineteenth century that any large series of cases was recorded. Even now the number of fully reported cases is not considerable and instances of the occurrence of these curious pathological conditions of the mesentery seem worthy of being placed on record. A good deal of light has of late years been thrown upon their origin but the text-books still contain little information upon the subject, and before proceeding to describe a case which I had the opportunity of observing it may be of interest briefly to review the present state of our knowledge.

The occurrence of various varieties of mesenteric cysts had long been recognised, but Hahn[1] in 1887 may be said to have been one of the earliest writers to publish a series of cases of sufficient number to justify an attempt at their logical classification. He divided mesenteric cysts into (1) sanguineous cysts; (2) chyle cysts; (3) serous cysts; and (4) echinococcus cysts. Braquehaye[2] shortly afterwards published a *résumé* of the subject and extended Hahn's list by adding to it: (1) congenital cysts (comprising chiefly dermoids but occasionally also cysts arising from the Wolffian body) and (2) cysts of the adjoining organs encroaching upon the mesentery. At the same time he proposes the term "lymphatic cyst" to include the chyle and most of the serous cysts. The list was from time to time still further amplified, as when Moynihan[3] included cases of (1) cystic malignant disease and, in a later paper,[4] (2) cysts with walls the structure of which resembles intestine. This classification was widely accepted until Dowd[5] in 1900 reviewed the whole subject and suggested a simpler and more rational classification in which all forms of mesenteric cysts were divided into three classes: (1) embryonic cysts; (2) hydatid cysts; and (3) cases of cystic malignant disease. The older classifications in the main were based simply upon the examination of the contents of the cysts or upon the structure of their walls. That suggested by Dowd, upon the other hand, is based upon the study of the origin of the cysts.

It had long been known that cysts of congenital origin occasionally were found in the mesentery. Cases of true dermoid cysts had been recorded by the earliest writers on the subject. Cohnheim attributed the origin of these dermoid cysts to the inclusion of aberrant portions of the ectoderm within the ovary in early fœtal life, and for a long time it was believed that all mesenteric dermoid cysts sprang from the ovary and only secondarily became mesenteric. This view seems to be disproved by Langton's case,[6] in which there were three dermoids—one in each ovary and one in the mesentery. The occasional occurrence of congenital mesenteric cysts in connexion with the Wolffian structures was also recognised a number of years ago. Later, when cysts were described with walls the structure of which resembled that of intestine, Brentano,[7] in 1895, hazarded the opinion that in some cases the origin of mesenteric cysts, apart from the occurrence of true dermoid cysts, must be ascribed to some congenital aberration. Eve[8] three years later more definitely expressed the view that such cysts were derived by some irregularity of development from the mesoblastic portion of the intestinal tube. The origin of certain varieties of mesenteric cysts was thus fairly well understood.

The great difficulty lay with the chylous and serous cysts. Rokitansky[9] as long ago as 1842 taught that mesenteric cysts originated in the lymphatic glands by the dilatation of lymph spaces into cavities which subsequently become transformed into single thin- and thick-walled cysts. Many years later Virchow[10] also expressed himself as inclined to attribute the origin of mesenteric cysts to degenerative processes in the lymphatic glands. The same theory was strongly supported by Pagenstecher[11] on the grounds of the discovery by himself and certain other observers of glandular tissue in the walls of some mesenteric cysts. He regarded the degenerative process leading to the formation of cysts as a chronic inflammatory hyperplasia characterised by hyaline changes and softening and believed the whole to be of tuberculous origin. Hahn[12] had somewhat earlier expressed the view that mesenteric cysts might arise not alone from changes in the glands themselves but also from the blocking of lacteals and chyle ducts. This view, which appears at the time to have found wide acceptance, was later corroborated by Carson[13] as the result of an analysis of 11 cases and as recently as 1901 found an advocate in the person of Blum.[14]

Dowd, in the admirable paper above referred to, recast the hitherto accepted views by showing that with the exception of parasitic cysts and cases of cystic malignant disease all forms of mesenteric cyst are embryonic in origin. Moynihan[15] states that congenital remnants of the Müllerian and Wolffian ducts and bodies and of the vitelline duct are regularly found between the layers of the mesentery. It seems probable that, as Dowd suggests, most mesenteric cysts are derived from the inclusion in the tissues of portions of these structures. In view of the rich anastomosis of the chyle vessels and of the fact that ligaturing the thoracic duct or its radicles does not produce the formation of cysts, it is highly improbable that mesenteric cysts should be the result of the occlusion of lacteals. Further, Pagenstecher[16] and others have described chyle cysts lined with epithelial cells. This could scarcely have been possible if the cysts had arisen, as was suggested by Rokitansky, from the dilatation of lymph spaces in the glands of the mesentery. The so-called "chyle cysts" therefore probably are embryonic cysts situated in such close relationship to the lacteals that chyle has been infused into them. "Serous cysts" are likewise preformed cysts of embryonic origin, closely corresponding in their structure and contents to those forms of ovarian and parovarian cysts which contain serous fluid. "Sanguineous cysts," which were formerly believed to be either the result of bleeding or traumatism of the mesentery, or of hæmorrhage into pre-existing chyle or serous cysts, are apparently preformed embryonic cysts into which hæmorrhage has taken place. Dowd believes that "cysts with walls which suggest intestinal structure" are probably derived from sequestrations or diverticula from the intestine. "Dermoid mesenteric cysts," which may show a structure exactly similar to that of the ovarian cystadenomata, are probably derived from the sequestration, during the early period of development, of portions of the ovary or parovarian body.

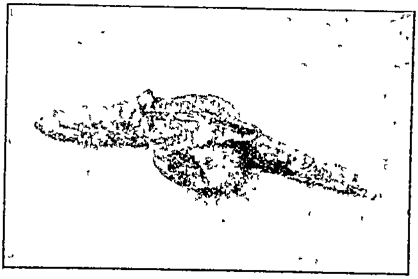
[16] Loc. cit.

In a word, then, all these cysts of the mesentery are preformed and of congenital origin, whilst the nature of their contents is largely a matter of chance. This view has since been accepted by Moynihan,[17] Fawcett,[18] and other recent writers on the subject. It seems to offer the most satisfactory explanation of the occurrence of mesenteric cysts.

Description of a case of mesenteric cyst.—The patient whose case I had the opportunity of observing was a female infant, aged eight months, who was admitted to the Hospital for Sick Children, Great Ormond-street, on Nov. 12th, 1902, as a case of intussusception. The mother stated that the baby had been in good health until Nov. 9th, when she began to vomit and seemed out of sorts. The sickness continued at intervals that day and the next. On the 11th the child grew very collapsed and the vomiting became almost constant. The mother now noticed that the vomited matter was brown and smelt like a motion. This state of affairs continued until the 12th when the child was seen by a medical man who diagnosed intestinal obstruction and at once sent the child to the hospital. Questions as to the condition of the stools elicited the fact that nothing had been evacuated from the bowels since Nov. 8th, when a normal motion was passed. No mucus or blood had been passed per rectum. Up to the onset of the present illness the child, who was breast-fed, had enjoyed good health. The patient, who was a fat, well-nourished infant, was admitted in an extremely collapsed condition. The abdomen was tumid and distended and there was felt an indefinite rounded mass to the right of, and a little above, the umbilicus. The diagnosis of intestinal obstruction due to intussusception was made and laparotomy was decided upon. Hot bottles were applied and an injection of half a pint of saline solution was made under the skin. The operation was performed shortly after admission by Mr. H. Stansfield Collier, to whom I am indebted for permission to use the clinical notes of the case. A small incision was made to the right of the middle line immediately above the umbilicus. Instead of an intussusception a tumour was felt pressing upon the small intestine. The incision was then enlarged and the tumour was brought more clearly into view. It was found to be a firm-walled cystic tumour of the size of a small apple, situated between the folds of the mesentery at the level of the lower end of the jejunum in which it had produced a kink. The tumour was drawn into the wound and, after being aspirated by means of a trocar and cannula, laid open with a scalpel. About an ounce of yellow viscid contents was evacuated. The gut below the level of the cyst, which had previously been empty and collapsed, immediately began to fill. Owing to the extremely collapsed state of the patient no attempt was made to remove the cyst. It was packed with gauze and replaced along with the bowel attached to it. Adequate provision for drainage having been made, the wound was closed and the child was hurried back to bed. 30 minutes after leaving the theatre breast-feeding was begun. The child never rallied. Seven hours after the operation she had a severe bout of vomiting and death occurred. Before death the temperature rose to 106° F.

On microscopical examination the fluid contents of the cyst were found to contain, besides a large quantity of amorphous débris, a number of cholesterin crystals. Owing to an unfortunate mishap the fluid was not preserved for chemical examination.

At the necropsy the organs generally were healthy. The cyst was of the size and shape of a somewhat flattened racquet ball, measuring two inches by one inch. It was situated between the layers of the mesentery of the jejunum with its longest diameter at right angles to the long axis of the bowel. The intestine coursed over, and was intimately attached to, the distal pole of the tumour. (See figure.) The bowel was not constricted and showed no unusual appearances beyond some smoothing out of the rugæ of the mucous membrane at the point of attachment. The cyst had firm walls, about a quarter of an inch in thickness, which cut almost like cartilage and did not collapse when an incision was made. Its inner surface was traversed by many fine trabeculæ of fibrous tissue and it contained a small quantity of blood-stained fluid; no hairs or other contents characteristic of dermoid cysts were discovered. The mesenteric glands were generally somewhat enlarged but they presented no evidence of tubercle.



Specimen of mesenteric cyst. A portion of the wall of the cyst has been removed and a bristle passed through the lumen of the gut attached to the distal pole of the tumour.

The tumour was examined histologically by Dr. F. A. Bainbridge, late clinical pathologist to the Hospital for Sick Children, who reported as follows: "On microscopic examination the cyst wall is seen to consist almost entirely of fibrous connective tissue on the outer surface of which are numerous blood-vessels and a layer of flattened epithelial cells (probably peritoneum). The inner surface of the cyst wall is slightly irregular and covered by several delicate layers of fibrin inclosing a few leucocytes between them. No muscular tissue is present."

There seems little doubt then, that we have here to deal with a cyst of congenital origin which must be classed among the group of embryonic cysts of the mesentery.

Harley-street, W.

AMAAS, OR KAFFIR MILK-POX.

BY W. E. DE KORTE, M.B. LOND.

AMAAS, or milk-pox, may be defined as a specific contagious, eruptive fever closely resembling small-pox in appearance, yet differing from it in some respects. The question which immediately suggests itself is whether the difference between small-pox and amaas is such as to constitute them distinct diseases or whether the latter is not variola modified by some undetermined factors. It has been also suggested that amaas is chicken-pox modified by race and climate. When contemporary epidemics of these two diseases are seen side by side, as occasionally occurs in the same community, the differential diagnosis presents little difficulty. The characters of the prodromata, of the rashes, and of the "clinical courses" of these two diseases do not appear to coincide. Moreover, the indubitable fact that vaccination immunises against amaas renders it well-nigh certain that we are not dealing with modified chicken-pox but, on the contrary, lends great weight to the view that amaas is closely allied to small-pox. As shown in a *résumé* of 13 cases appended, the fact that it was possible to vaccinate, though only in a modified degree, convalescents from amaas would indicate that the disease in question is not ordinary European variola, "for at Glasgow during five years 52 small-pox patients were vaccinated at various periods during the stages of eruption and convalescence twice, or even thrice, but in no single instance was any reaction manifested."[1]

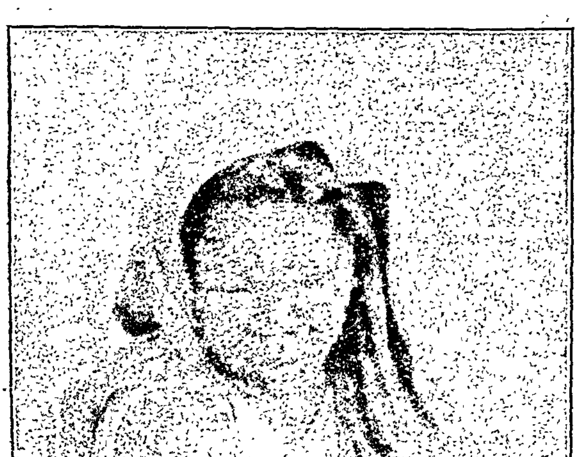
---

[17] Medical Chronicle, September, 1902, p. 345.

[18] Transactions of the Pathological Society of London, 1902, vol. liii., p. 406.

The following were the differences observed between variola and amaas:—1. The predilection of amaas for the aboriginal native rather than for the half-caste, both living under similar conditions and both being unvaccinated, and the almost entire immunity of the European even though unvaccinated. Thus, in Graaff Reinet, Cape Colony, where these notes were made, out of 125 cases admitted to the lazaretto only two occurred in poor whites, yet the surroundings of these unfortunates are for the most part quite as unsavoury as those of the natives. 2. The low mortality for all ages among the unvaccinated. Thus, of 97 cases admitted to the local lazaretto, where the patients were huddled together on the floor, without nursing of any kind, and reduced to the utmost shifts, only three deaths occurred which could fairly be ascribed to the disease. Thus the mortality for this particular series of cases was only slightly over 3 per cent. 3. The disease is milder among sucklings and children than among adults, frequently aborting in the former. It cannot be conjectured that some degree of immunity had been conferred on the nurslings by vaccination of their mothers during the period of gestation, for in no instance could it be ascertained that vaccination had been so performed. 4. The absence of secondary fever in amaas, even in confluent cases. Pustulation occurs much earlier and is a more gradual process; the degree of pus formation is also less than that observed in small-pox. 5. The nature of the resulting scar. Instead of the depressed foveate scar of small-pox, amaas, when it does scar, which is by no means always the case, leaves an irregular, stellate depression the edges of which present a worm-eaten appearance. 6. The vesicle is not so completely loculated as in variola, though partially divided by fine trabeculæ. 7. Owing to the spread of the epidemic the magistrate ordered the vaccination of all coloured natives. About a dozen cases were admitted to the lazaretto displaying vaccinia and amaas (Fig. 1), neither disease being apparently modified by the other. It can definitely be said that amaas was not aggravated by the superimposed vaccinia. The type assumed by the major disease in pre-vaccinated cases was neither more nor less severe than the ordinary run of cases and certainly not nearly so severe as occurred in some unvaccinated sufferers. In juxtaposition to the observation that the simultaneous development of the eruptions of the two diseases occurred in the same person is the fact that the course of vaccinia in the subjects of amaas, after the latter disease has run its course, is undoubtedly delayed and modified to a varying degree in all those experimented on. The vaccinations were done between the third and fifth weeks after the commencement of the eruption. Whether, therefore, at a later date the tissues contain more of the antitoxic or anti-microbic substance for neutralising the poison of vaccinia cannot be said to have been determined. An assumption of this kind, however, is negatived by the observations of Dr. H. Sinigar of Leavesden Asylum who reports: "Out of 45 persons who provided evidence of previous small-pox 40 were successfully vaccinated."[2]

FIG. 1.



From a photograph of a patient showing the eruption of both vaccinia and amaas.

As only patients in an advanced state of amaas were brought to the lazaretto and owing to the impossibility of extracting the sequence of events in the development of their complaints from raw Kaffirs there was for a while considerable obscurity as to the clinical course of the disease in its earlier stages. A case occurring in private practice in a white patient afforded an opportunity of observing the various stages of the disease.

A girl, aged three years, unvaccinated, suffering with a cold in the head and running at the nose for several days, complained of sore throat for 24 hours. The glands of the neck were tender and slightly enlarged. On the second day of the disease the temperature was 105° F and the child vomited and was seriously ill. On the third day of the disease a few acne-like spots appeared on the bridge of the nose, on the backs of the hands, and on the flexor surfaces of the forearms. The temperature was 102°. (When time is stated in terms of hours it refers to the period which had elapsed after the beginning of the eruption.) At the twelfth hour the eruption covered the back and the limbs; there were only a few spots on the front of the chest and abdomen. The eruption felt shotty and consisted of an irregular macule with a small conical central elevation, yellowish in colour. At the twenty-fourth hour the temperature was 98·4°, the rose spots were more papular, and where the papules were close together their areolæ coalesced. At the thirty-sixth hour the central little cone had grown to a flat-topped vesicle. At the forty-eighth hour most of the papules had become flat-topped vesicles. At the sixtieth hour most of the vesicles had a depressed centre; a few were dome-shaped. The temperature was 102°. There was some eruption in the nose, throat, and ear. There were considerable itching of the skin and conjunctivitis. At the seventy-second hour the vesicles were somewhat larger; the other characters were the same. At the ninety-sixth hour the vesicles were decidedly pearly in appearance and dome-shaped; pustulation was commencing. A few vesicles, especially on the face, were more fully pustular. The temperature was 100°. The rose-red areola was confined as a narrow band to the base of the vesicle. In severe cases, however, the areola extends for some distance round the pock. At the hundred and eighth hour the temperature was 102·4°. The vesicles were losing their pearliness and were becoming more waxy-white in colour. At the hundred and twentieth hour a considerable number of the vesicles were only sero-purulent and devoid of any areola. The temperature was 101°. Pustulation might be said to be complete at the hundred and twentieth hour. At the hundred and thirty-second hour the temperature was 101°. The patient was much better and ate and slept well; her recovery from this time was uninterrupted. At the hundred and forty-fourth hour the temperature was 100°. Most of the pustules on the face and back had ruptured; those on the face which were not broken were beginning to scab. Most of the pustules on the legs and the arms had collapsed without any scab formation; a certain proportion, however, scabbed over.

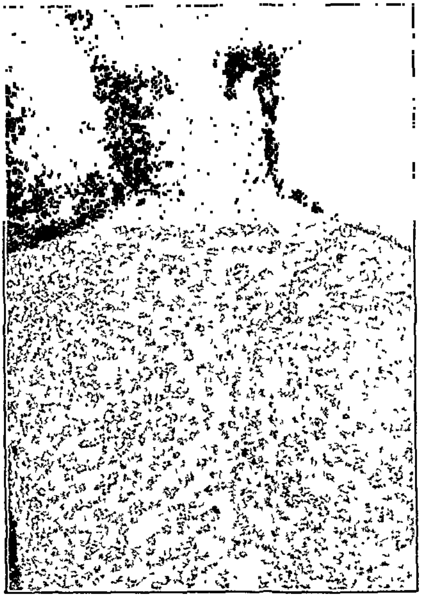
---

[1] Dr. R. S. Thomson and Dr. J. Brownlee: THE LANCET, Oct. 22nd, 1898, p. 1051.

[2] THE LANCET, April 5th, 1902, p. 951.

The process of collapse and scab formation is as follows (*vide* Fig. 2, which shows the back of a white man covered with the pustules of amaas). It will be seen that a small dark dot occupies the centre of each pock. This appearance is due in part to umbilication and in part to alteration in texture of the wall of the pustule at this spot. The centre of the dome of the pustule becomes bluish in colour and slightly depressed; a rent occurs in this depression through which some of the contents escape. The walls of the collapsed pustule together with the inspissated contents are separated at the base of attachment and shed as a small brownish scale, exposing to view a somewhat raised floor, dusky red in colour, which fades on pressure. After some further changes in the European a pigmented stain persists for some time, while in the native, owing to the destruction of the rete Malpighii and its contained colouring matter, a white spot surrounded by a halo of dark pigment marks the site of the pock. The patient whose case I have just narrated being a highly neurotic subject the course of the temperature is probably not typical. The natives suffer from coryza, headache, backache, and a high temperature for three days, on the third day the rash appears, and from that [illegible] this is the usual run of case. Much severer examples occur in which the symptoms are greatly aggravated, the disease becomes confluent but only on the face and legs, rarely on the arms or trunk. At the height of the pustular stage there is much subcutaneous œdema. The lips, the nose, and the eyes are much swollen. The mouth remains open and saliva trickles out. The eyes can hardly be opened. The general contour of the face is so altered as to make the patient unrecognisable. The teeth and gums are covered with sordes. The tongue is harsh and dry and the breath is foul, the patient presenting a most loathsome appearance.

FIG. 2.



Eruption of amaas on the back of a white man.

The following is the vaccination history of two European children, three native adults, and nine native children, all of whom were convalescing from amaas at the time of the vaccination.

CASE 1.—A boy, aged 12 years. He had been vaccinated on two previous occasions unsuccessfully. There were no vaccination marks. During the fourth and fifth weeks after the eruption of the disease he was twice vaccinated with humanised lymph without the least effect. A week later, on Oct 2nd, he was vaccinated in three places with fresh calf lymph. On the 9th one well-marked vesicle with slight areola occupied the site of each insertion. On the 11th one vesicle had disappeared; the other two were scabbing over. He presented the appearance of a reaction on a person already partially protected by vaccinia.

CASE 2.—A girl, aged three years. This patient had never been vaccinated. Four weeks after the date of the eruption she was vaccinated with humanised lymph; no result followed. On Oct. 2nd she was revaccinated with calf lymph. On the 9th there were two well-marked vesico-papules. On the 12th a small red vascular papule marked the site of each inoculation—a reaction precisely similar to the previous case. It is interesting to note that neither of these children reacted to human lymph while both did to calf lymph. Arm-to-arm vaccination in two subjects of the disease experimented upon took in the manner described.

CASE 3.—This patient was an adult red Kaffir who was vaccinated for the first time with calf lymph, strict antiseptic precautions being adopted. A photograph showed well-marked vaccinia eight days after inoculation, also the sites of the pocks seen as white dots due to absence of pigment surrounded by dark rings caused by increased pigmentation. This patient—the only one—presented a typical areola, so that the reaction in this case was complete. The patient had been 24 days at the lazaretto when vaccinated.

CASES 4 AND 5.—These patients, two women, were vaccinated for the first time on June 28th. A photograph taken on July 8th showed both patients presenting typical vesicles having raised edges and central depressions. The slow evolution of the vaccinia was probably due to the modifying influence of the amaas and not to attenuation of the lymph employed.

CASE 6.—A girl, aged three years, vaccinated from Case 3 on one spot which developed into typical vaccinia.

CASE 7.—This patient was vaccinated with the rest on Sept. 30th for the first time. On Oct. 7th there were three vesicles, one on each vaccinated area. On the 16th there were two scabbed pustules; one vesicle had disappeared.

CASE 8.—A boy, aged three years. On Oct. 9th there was one vesico-papule on each of the two vaccinated spots; the third insertion had disappeared.

[illegible] years. On Oct. 7th she had [illegible] The vesicles had coalesced; [illegible] ed to the base of the vesicles. The vesicles were very vascular. On the 15th the vesicles had become three scabbed pustule; there was no areola.

CASE 10.—A boy, aged three years. On Oct. 7th there were well vesiculated areas without roseola. On the 11th the vesicles had run together; there was no roseola. The vesicles were very vascular. On the 16th there were three scabbed pustules; there was no areola.

CASE 11.—This patient was aged ten years. On Oct. 8th there were three small papules. On the 11th no vesicles had formed and the papules were quite distinct; there was no areola.

CASE 12.—A girl, aged one year. On Oct. 11th a single vesicle occupied the site of each insertion.

CASE 13.—A girl, vaccinated on Oct 7th. On the 16th there was a papule on the site of each of two insertions; the third had disappeared.

CASE 14.—This patient was vaccinated on *Oct. 16th in* three places with lymph taken from the patient in Case 10. On the 23rd one of the above insertions had developed into typical vaccinia. The quantity of lymph obtained from the patient in Case 10 was very little, probably not sufficient to have produced more than the above result.

Summarising the above, with the exception of the patient in Case 3, who gave as complete a reaction as an ordinary primary case, all reacted in varying degrees, like individuals more or less protected by previous vaccination.

Bacteriology.—As might be expected, this is of a negative kind. Smears on cover-glasses made from the contents of the pock at all stages disclosed no organism which could in any way be connected with the disease. If proper precautions were taken to prevent the admixture of any extraneous organism in the collection of the amaas matter

A Comparative Table of Small-pox, Amaas, and of Two Diseases of a Varioliform Nature which have been Described by Dr. Brownlee and Dr. Thomson and by Dr. Izett W. Anderson.*

—	Amaas.	Natural small-pox.	Infectious disease in Lascars.	Varioloid varicela.
Incubation ...	10 to 14 days.	10 to 14 days.	10 to 14 days.	14 days.
Effects of vaccination and previous attacks of variola ...	Sure preventive. Only one case occurred, in a woman, aged 63 years, who had suffered from small-pox 60 years previously and bore unmistakeable evidence of the attack.	Sure preventive. Second attacks rare.	In 11 cases previous vaccination had no immunising effect. Previous attacks of variola seemed to have little controlling effect.	Disease occurs equally in vaccinated or unvaccinated persons. It occurred in those deeply pitted by antecedent small-pox.
Effects of vaccination during convalescence	Modified vaccinia.	None at all.	Four out of five patients were successfully vaccinated; the fifth failed; this patient had previously suffered from small-pox.	Not noted.
Date of eruption	Third day.	Third day.	First day.	In the course of the third day of the disease.
Distribution of rash on the body ...	The body generally, not uniformly; always most markedly on the face, front of the legs, extensor surfaces of the forearm, palms of the hands, and soles of the feet.	As for amaas.	No special affinity for the face. No eruption on the palms of the hands and soles of the feet. On the legs elements were more sparse and scattered. The back was chiefly affected.	—
Initial rashes	Were not observed.	Occurred.	Not mentioned.	Not mentioned.
Evolution of the pock ...	In from 36 to 48 hours the macule with its small conical centre has passed through the papular stage and has become a fully developed flat-topped vesicle. The vesicles are partially divided by fine trabeculæ. In 96 hours the vesicle is pearly and in 100 hours is waxy-white in appearance. The polynuclear lymphocytes are losing staining reactions and becoming pus cells. A number of pustules are without areolæ. Umbilication and pseudo-umbilication are present.	Vesicle attains limit of its growth about the fifth day of the eruption. Loculated. Pustule formed on the eighth or ninth day surrounded by a vivid areola. Umbilication present.	Vesicles almost entirely absent; such as do exist resemble small bullæ such as might have been produced by scalding water. Vesicles partially divided by fine trabeculæ Vesicular contents originally clear become cloudy and distinctly sero purulent; but in no instance were true pustules formed. Pseudo-umbilication produced by desiccation of central portion of vesicle.	Papular stage lasts from 24 to 48 hours. Eruption presents papular and vesicular stages and only in some cases the pustular stage. Vesicles in some cases resembling those of variola and in others those of varicella. Umbilication was not constant.
Fever	Defervescence with first appearance of eruption. No secondary fever.	Defervescence with first appearance of eruption. Secondary fever.	No defervescence as in variola. No secondary fever.	The temperature was of a remittent type without secondary fever.
Race and age	Predilection for individual negroes in unvaccinated community, also individual Europeans but in much lesser degree. Disease mild in sucklings and children, often aborting in former. Fatality for all ages is low.	All unvaccinated persons susceptible with trifling exception. Very fatal to children under five years. Fatality for all ages is high.	Confined to Lascars. Out of 250 English workmen exposed to infection not one contracted this disease. No mortality.	Chiefly among natives. Europeans susceptible. (?)
Initial symptoms... ...	Headache, slight cold in the head, slight sore throat, glands of the neck enlarged. Vomiting and occasional backache.	Backache, headache, vomiting. Sore throat and enlarged glands not usual.	—	Constant catarrh of the throat, with eruption on the soft parts.

* Dr. Izett Anderson: Epidemic Varioloid Varicella in Jamaica, Transactions of Epidemiological Society of London, vol. ii., p. 414.

no organisms could be discovered in the contents of the vesicle or pustule. Nor could any cultivation be obtained on the ordinary culture media. The following organisms were very often present in specimens of amaas lymph: staphylococcus pyogenes aureus, staphylococcus cereus flavus, staphylococcus albus epidermidis, and bacillus subtilis. By first washing the pock with a strong solution of an antiseptic and passing a sterile capillary tube into the interior of the pock its contents could be collected free from all contaminating organisms. With regard to experiments made on animals eight guinea-pigs were found apparently to be immune to the action of amaas lymph, whether inoculated as vaccine or injected into the peritoneal cavity. Experiments on calves were inconclusive but nothing like typical vesicles were produced by inoculating these animals with amaas lymph. A subcutaneous injection of two drops of amaas lymph was given to a monkey without producing any visible effect. To ascertain whether the injection of amaas matter had exerted any influence on the monkey[3] it was subsequently vaccinated with calf lymph on the back. By the fifth day a number of vesicles made their appearance; some of these ran together but showed no umbilication. There fever in amaas, The axillary glands were slightly enlarged. much earlier alay brown scabs had formed on what had now pus formation is which were involuting. The result was 5. The nature q have expected had the monkey been prodepressed foveate s vaccination. This animal undoubtedly scar, which is by in exactly the same manner as human irregular, stellate dc have had amaas.

Summarising the appended table, it is evident that amaas cannot well be confounded with either the infectious disease in Lascars or with varioloid varicella. When compared with variola such a definite statement cannot be made, for it will be seen that amaas resembles small-pox in many particulars; the differences which exist between these two diseases appear to consist more in degree of virulence than of kind.[4] The provisional conclusion arrived at on the relationship of amaas to variola is that the former is small-pox mitigated by some undetermined factor or factors.

Graaff Reinet, Cape Colony.

A CASE FOR DIAGNOSIS.[1]

By W. JOHNSON SMYTH, M.D. Edin.,
LATE SENIOR MEDICAL OFFICER, KENT COUNTY ASYLUM, MAIDSTONE.

The patient was apparently in good health till three and a half years ago when the train by which he was travelling was derailed at midnight. Early next morning he was alarmed to find himself lying between two dead fellow passengers and five days after this his ill-health began. This consisted in frequent vomiting, followed by great loss of strength and in his being invalided home. During the interval elapsing between the railway disaster and last autumn he had been under the care of 20 medical men and the symptom of vomiting could be relieved only by the hypodermic administration of morphine, although many other remedies had been tried. His family medical adviser recommended his relatives to send him to Switzerland and he had reached London late last year in charge of a nurse who had instructions to give him half a grain of morphine whenever vomiting set in. The patient, however, had a considerable sum of money in his pocket and being fond of a gamble put most of this on a horse with unfortunate results. The vomiting set in with exceptional severity and only large doses, from a half to one grain, of morphine relieved him.

[4] Cf. Notes on a Mild Type of Small-pox, Variola Ambulans, by Dr. F. Montezambert, Brit Med. Jour., May 11th, 1901.

[1] A paper read before the Bournemouth Medical Society on March 9th, 1904.

Such were the circumstances of the case when I was asked to take charge of the patient. He came under my care direct from London. He complained of frequent attacks of vomiting, headache, insomnia, or when asleep of nightmare or sensuous dreams. He admitted having had syphilis six years previously; he believed that he had received mercurial treatment, though for a short period. His habits were temperate till the present trouble began. He was unmarried, aged 38 years; his height was 5 feet 8 inches, and his weight was 8 stones 6 pounds. He was much emaciated. As regards the cerebro-spinal nervous system much emotional weakness was evident. The will was infirm to a high degree. His memory was good but his judgment was diseased. His ideas were grandiose; he talked as if he had very ample means, which was untrue, and he was extravagant in every direction of thought. He was harmless to others but he often talked of suicide. He informed me that his people wanted to get him certified as insane but that no medical man would risk it. I certainly considered him fairly on the borderland, if not within [illegible] He suffered from a slight degr [illegible] was twice as large as the right, [illegible] was circular and free from puckering. He suffered from associated iridoplegia in the left eye, the iris responding to neither light nor accommodation for distance. The other organs of special sense were normal. From a later examination of the retinæ they were found to be free from syphilitic or albuminuric deposits. Impulses through the motor nerves were feeble, badly sustained, and this was most marked in the lingual, labial, and facial muscles. He had an occasional difficulty in starting a sentence. The function of the sensory nerves was exalted throughout. The knee and other deep reflexes were exaggerated. The superficial reflexes were the same. No girdle pains were complained of at this stage. The muscular sense was preserved. There was much wasting of the muscles but quite symmetrically so throughout the body. A distinct cautiousness of gait was noticeable but the ataxia was not marked. The temperature was normal when first seen but there was a rise of from 1° to 1·5° F. every evening. The integumentary system was normal. There was no albumin or sugar in the urine which was normally acid with a specific gravity of 1020 The patient complained of frequently vomiting food and when there was no food present in the stomach he vomited watery, bile-stained material. Because of the severity of this symptom he said he had often to be fed per rectum for days at a time. Later I made careful observations as to the nature of the vomit. It contained food, hydrochloric acid, and bile pigment, but no blood at any time. No fæcal matter was ever vomited. On examining the abdomen nothing abnormal could be found nor was there pain on pressure over the stomach or elsewhere. He suffered from occasional constipation but the stools were natural in form and colour; blood was never noticed. No hæmorrhoids were present. The heart and the lungs were quite normal.

I made a close inquiry from the nurse and, whilst she corroborated the history of vomiting as narrated by the patient, she alleged that the patient, in her opinion, had the power to induce vomiting at will and did so in order to get the morphine. On my suggesting that she might go away she said that the patient "would howl his head off" if she was not at hand to give him morphine. I got rid of the nurse on the next day. The patient received a severe "talking to" and I insisted on his playing a "straight game" or else I would not attend him. He was allowed a glass of benedictine before meals (not a bad remedy for mal de mer). He was given a mixture of bromide of potassium and syrup of glycerophosphates three times a day after meals. He had an hour's massage commencing at 10 P.M.

For six weeks no vomiting took place, the patient slept well and put on six pounds in weight but all the other signs remained the same. At the end of this period I had to leave Bournemouth for ten days but asked a medical friend, who [illegible] absence, not to give morphine, [illegible] As soon as the patient heard that [illegible] sick, sent for my medical friend, and swore by "bell, book, and candle" that I promised faithfully that if he got sick during my absence he would get morphine. My substitute refused the morphine but the patient declared that he would jump out of the window if he did not get the drug. So to prevent this my friend gave half a grain of morphine hypodermically. During those ten days the patient had a daily return of sickness and was given morphine once or twice a day, never more than half a grain at a time.

On my return I was surprised at the turn that things had taken and I found the patient suffering from the most distressing form of vomiting I ever witnessed. Ice, chloroform, chloretone, and hot drinks were tried but in vain; the sickness continued and at this stage the patient for the first time complained of acute neuralgic pains around the lower ribs. Morphine alone seemed to give relief. The morning temperature was 101° and the evening temperature was 102·2°. So great was his distress that I feared acute mania would develop. During the four days that elapsed from my return the patient was given three grains of morphine whilst feeding per rectum was constantly carried out, as his stomach would retain nothing. On the fourth day he had a very violent attack of pain and vomiting and half a grain of morphine was given at 3 P.M. At 4 30 I was sent for, as the patient appeared to be dying. I found him unconscious; Cheyne Stokes breathing had set in and the end seemed to be near. There was no sign of contraction in either pupil, both being equally dilated. I injected one-sixtieth of a grain of strychnine and 40 minims of ozonic ether, after which the respiration and the pulse improved slightly. A medical friend saw him at 5 P.M.; we injected more strychnine and ether and though the patient rallied temporarily he again got worse and apparently died at 5 30 P.M. After observing the respiration and cardiac movement cease we stretched the limbs into position, covered him up somewhat, and had been some time discussing the case when to our horror the patient gave a long inspiratory snore that somewhat disconcerted us. I think the respiratory and cardiac movement must have been quite two minutes in abeyance, during which period the corneal and plantar reflexes were quite gone and the pupils were widely dilated. On this renewal of respiration and circulation taking place we administered hot nutrient enemata and with an occasional dose of strychnine, digitalin, and ether the patient was kept alive till 9 P.M. on the second day after his apparent death. During this period he recognised his relatives and myself, his corneal and other reflexes returned, but the Cheyne Stokes breathing continued less or more till the end. He was unable to swallow food during this time and his speech was unintelligible. I most carefully examined his retinæ during this period; apart from enormous congestion of the blood-vessels they were quite normal.

On the day following death I made a post-mortem examination of the brain. The meninges were deeply congested and the pia mater and arachnoid were matted together, thickened, and milky in appearance over the frontal and anterior half of the parietal lobes, to which they were closely adherent. The grey and white matter was congested; the lateral ventricles were dilated and contained excess of fluid. The choroid plexuses were enlarged and had a beaded and gelatinous appearance. The brain substance as a whole was preternaturally soft. *No hæmorrhage, gumma, or tumour of any sort was present.* Professor W. S. Greenfield of the University of Edinburgh kindly examined the medulla for me but found no evidence of disease in it.

The following are some of the points of interest in this case, 1. The onset of the leading symptom—vomiting—began soon after the railway disaster. 2. It is evident that morphinomania was fairly established. 3. Did the morphinomania exaggerate the vomiting? Certainly, the latter was apparently kept in obeyance by the treatment which the patient received during the first six weeks he was under my care. 4 Was the case one of locomotor ataxia, general paralysis, or some other disease? Most of the subjective and objective symptoms apply equally to locomotor ataxia and general paralysis, whilst if, on the one hand, the vomiting and the girdle pains point to locomotor ataxia, the exaggerated knee-jerks, the mental deterioration, and the post-mortem appearances point to general paralysis. Personally, although I certified the death as due to locomotor ataxia, I believe it to be one that goes far to sustain Dr. F. W. Mott's view (as mentioned in the *Archives of Neurology*) that the older clinicians were in error in describing two diseases locomotor ataxia and general paralysis, there being only one disease here—"tabo-paralysis"—the former being varieties of the latter. I think that the patient's final collapse was due to an acute congestive attack—severer than ever he previously experienced—commencing in the medulla, at first involving the vomiting centre, and, after paralysing this, exciting and then paralysing the respiratory centre that lies close by.

Bournemouth.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SEPTIC PNEUMONIA; ABSCESS OF THE LUNG; ASPIRATION; RECOVERY.

By ARTHUR J. SHARP, M.D. LOND., F.R.C.S. ENG.,
AND
HUGH N. KEELING, L.R.C.P. LOND., M.R.C.S. ENG.

THE patient was a single woman, aged 31 years. Her family history was good with the exception that one sister died at the age of 41 years from phthisis, another at 37 years from heart disease following rheumatism, and a third at 34 years from "consumption of the bowels." She was a tall, thin woman, with a sallow complexion and had enjoyed good health with the exception of occasional colds. During the summer of 1903 she felt out of sorts—a little overworked and noticed that her breath was foul owing to numerous carious teeth and stumps. On Nov. 18th, 1903, the unsound teeth were extracted under ether, both the administration of the anæsthetic and the subsequent recovery being uneventful. The dentist was struck by the unusual fœtor about her mouth. She returned to her employment three days later, there being neither cough nor expectoration at this time. On the 27th she had a rigor in the evening and was seized with severe pain below the right nipple. On the next morning there were no abnormal physical signs discoverable; her temperature was 100° F.; her pulse and respirations were respectively 92 and 24 per minute. The diagnosis was acute pleurisy, probably of the phrenic surface of the lung. Two days later a short cough commenced, with limited expansion of the thorax on the right side. On Dec. 2nd her temperature was 100° and the pulse and respirations were respectively 96 and 20 per minute. The pain was less and the expansion was better. There were slight impairment of resonance and deficient entry of air at the right base behind. The resonance elsewhere was good. On the 4th her temperature was 102·8°, her pulse-rate was from 100 to 112, and her respirations were 32 per minute. There were increased dulness at the right base behind and a slight friction sound below the nipple in front. There was no expectoration. On the 6th the middle two-fourths of the right lung posteriorly showed impaired resonance and in places there was tubular breathing. On the 7th some extremely offensive expectoration appeared for the first time. An aspirator trocar and cannula three inches long driven deeply through the ninth intercostal space considerably posterior to the scapular angle (the only place where there now seemed to be any dulness) was felt to move freely within a cavity and two and a half ounces of horribly foul pus were evacuated in this way, suction being strongly maintained until only blood was forthcoming. A diagnosis of localised empyema was made and the patient was removed to a hospital. It is noteworthy that her temperature was practically normal from this date onwards, although her general condition was exceedingly critical for some days. On the 8th an operation as for empyema was performed by resecting the ninth rib. Although a bead of dried pus could still be seen clinging to the cutaneous end of the track of the aspirating cannula no infection of the pleura appeared to have taken place. Some serum escaped from the pleural cavity when opened, but though the lung was punctured once or twice nothing further abnormal was found. During the next few days the patient had recurrent bouts of cough, during which the odour of the breath and sputum were indescribably foul. In the intervals of these attacks it was noticed that the breath and sputum both remained (or gradually became) free from distinctive odour. The operation wound continued inodorous throughout, the patient gradually began to recover strength, and the sweating, cough, and expectoration diminished. On Jan. 4th, 1904, four weeks after the aspiration, abnormal physical signs were only to be found over an area three inches or less in diameter at the site of the puncture, and here the breath sounds, voice sounds, and resonance were all somewhat deficient. She was discharged on the 5th and within the next ten days the cough entirely ceased.

Considering the foul state of the mouth when the teeth were extracted it is easy to suppose air-borne infection to have taken place, but it is difficult to understand how the dental operation could have been avoided. Presumably the risk would increase with long postponement. It is interesting to note that simple aspiration may (as in this case) suffice, since subsequently to the aspiration recovery was speedy and uninterrupted and the quantity of sputum expectorated was insignificant. At the end of April she was in good health.

Whitby, Yorkshire.

NOTE OF A CASE OF SHOULDER PRESENTATION ENDING BY NATURAL DELIVERY.

BY THE RIGHT REV. J. E. HINE, D.D. OXON., M.D. LOND.,
BISHOP OF ZANZIBAR.

I HAD read years ago in books of cases of this kind ending satisfactorily by the *vis medicatrix naturæ* but I had not myself seen one, and the circumstances of the present case being somewhat unusual it seems worth while sending a note of it to THE LANCET.

I was staying last January in a remote village on the mainland in the Yao country of Central Africa near the Rovuma river. Late at night I was asked by a native teacher to go to see a woman who had been in labour for two days and the people did not know what to do to help her. I may say that it is very unusual for the natives in this part of the country to call in any outside assistance for women in labour. The greatest secrecy is kept and the matter is intrusted to certain wise women of the village and no man is allowed to approach anywhere near the scene. This particular woman, however, was a Christian, the wife of a teacher, and the native prejudice on his side, at any rate, was not so marked as usual. I went with the messenger and was taken about a mile into the forest, my progress being interrupted from time to time by sorties of excited women who tried to prevent my going. However, I got at last to the place and found the patient lying out in the open beside a wood fire with a group of women (whether wise or not wise I should not like to say) sitting round her. She was a young girl, not more than 16 years old, a primipara. Labour had come on at full term more than 48 hours previously and the membranes had ruptured some hours before I arrived. The right arm of a fully developed though evidently dead but not decomposed fœtus was prolapsed, lying outside the vulva. I had great difficulty in getting the people to let me make an examination but after a time I succeeded and found that the os was only dilated sufficiently for the passage of the arm, the uterus was firmly contracted down on the fœtus, and all labour pains had ceased. The patient was in fairly good condition. The pulse was regular and not very weak and there was no very marked distress. It seemed, however, to me that the condition looked about as unfavourable as it well could. I had no chloroform and no instruments of any kind with me and anything like operative interference, or manual interference either, was impossible under the circumstances. I told the woman and her friends that I did not see that I could help her, but I gave her a grain of opium more for the sake of "doing something" than with any hope of relief. It appeared to me perfectly impossible that delivery could take place under the conditions—a transverse presentation, a young primipara, a fully developed fœtus, a rigidly contracted uterus, and more than two days in labour. So I dropped the medical character and assumed the priestly and prepared her for death which seemed to me inevitable. I then went away and left her. About an hour aftewards a messenger arrived and told me that the child had been born; nothing more had been done but pains had come on and delivery had taken place. On the next morning I went to see the mother and found her sitting up with a group of friends round the fire in her hut looking quite comfortable as if nothing particular had happened. What actually did happen I could not find out. My questions spoken in Swahili had to be translated into Makua and the difficulty of expressing technical terms and translating untechnical answers through media of this kind is a very great one. Whether the favourable result was ascribed to the miracle-working powers of the bishop, or whether it was the grain of opium, or whether it was due to some native charm I could not find out. It all ended happily. One sees strange things in the untrodden wilds of Africa!

Masasi, German East Africa.

A CASE OF CARBOLIC POISONING IN AN INFANT.

By LOUIS E. STEVENSON, B.A., M.B., B.C. CANTAB.

I CIRCUMCISED an infant, six weeks old, on March 10th of this year. The wound was dressed with lint soaked in carbolic oil (1 in 20). The little patient was very well all day, sleeping most of the time, and had a good night. Early next morning he vomited and had apparently nausea at intervals during the day but did not vomit any more. He had two normal motions. During the afternoon the napkins were stained a dark colour. The carbolic dressing was discontinued. On March 12th he was rather restless with no sound sleep. The appetite was poor and the urine was scanty and dark-coloured. He had two motions, one of which was dark in colour. Towards evening the urine was more free and his appetite was better. He had a very restless night, scarcely sleeping at all. On the 13th the patient was very restless. He had a temperature of 98° F.; the urine was passed freely and the motions were normal. The eyes had a glassy appearance with the eyelids somewhat injected. He was pallid but had a fairly good appetite. He had twitchings in the limbs at intervals all day. He slept better at night. On the 14th the same symptoms continued. At 6 P.M. there was a slight rose-coloured rash on the chest and the abdomen. The rash occurred in patches. He slept well. On the 15th the rash was very thick over the chest and the abdomen. At 9 A.M. the child became extremely pallid with feeble pulse. He was ordered brandy, five drops every two hours. He had a second fainting attack about 11 A.M. His temperature was 98°. His appetite was good. He had no more attacks, although he remained very pale all day. At 6 P.M. the rash on the chest and the abdomen was disappearing but a slight rash developed on the back. He slept well. On the 16th the rash was very thick on the back and very slight on the hips, the neck, and the face. The patient was happy and contented. The pallor was still marked. On the 17th the rash was almost gone. The eyelid injection and the glassy appearance of the eyes were rapidly disappearing. The child became convalescent from this date.

For these excellent notes I am indebted to Nurse Adams who watched the little patient most carefully and nursed him with rare skill. The lesson to be drawn from this case is, I think, that in view of the possibility of absorption one should use very much weaker carbolic oil in these cases or substitute some other dressing. I have used the 1 in 20 carbolic oil in a considerable number of cases of circumcision and have never known a case of poisoning before. I shall be interested to hear from other practitioners if they have experienced any trouble of this kind.

ST. GEORGE'S HOSPITAL.

THREE CASES OF PROSTATECTOMY.

(Under the care of Mr. H. W. ALLINGHAM.)

FOR the notes of the cases we are indebted to Mr. T. Crisp English, surgical registrar.

CASE 1.—The patient, aged 75 years, was admitted into St. George's Hospital on Nov. 16th, 1902, with epididymitis, the result of catheterisation for enlarged prostate. He had had prostatic trouble for about seven years and for the last two years had passed a No. 7 black olivary catheter for himself, using it about three or four times a day and three times at night. There had always been severe pain before catheterisation and also pain after it, with occasional hæmaturia, and the patient was very anxious for any operation that could afford him relief, for "his life during the last two years had been perfect misery." Five weeks before admission there had been acute epididymitis on the right side, which had subsided, and this was followed by similar inflammation on the left side.

On admission the patient was found to be in fair condition and a rectal examination showed marked enlargement of the prostate. He was suffering from a great deal of pain and the catheter when passed was frequently blocked by small clots of blood; a little urine could sometimes be passed without the use of an instrument. A consultation was held and prostatectomy was recommended. This was performed on Nov. 27th by Mr. Allingham. A No. 8 catheter was passed and the bladder was distended with boric lotion. Suprapubic cystotomy was then performed and the enlarged middle lobe of the prostate was found to project prominently into the bladder. Mr. Allingham then proceeded to enucleate the prostate with the right index finger, standing on the patient's left side. After about five minutes' work the whole prostate was removed from the bladder, together with the proximal one and a quarter inches of the urethra which was wide and tortuous. There was very little hæmorrhage and the prostate came away as one piece. A large tube was placed in the suprapubic wound and a No. 8 catheter was tied into the urethra. Progress after the operation was at first very satisfactory, the pain being entirely relieved and small quantities of urine being passed per urethram. On Dec. 20th, however, acute bronchitis developed, with gout in the feet and right shoulder, and death occurred on the 27th.

CASE 2.—A man, aged 64 years, had suffered with increased frequency of micturition for six years. During the last three months there had been increasing difficulty in micturition until ten days before admission when acute retention occurred. Since that time he had only passed drops of urine with great pain. On admission into St. George's Hospital on March 25th, 1903, the patient was catheterised and about two pints of urine were withdrawn. This was alkaline and contained albumin and pus. The prostate was felt projecting into the rectum as a large, rounded, tender tumour. For four weeks he was regularly catheterised and the bladder was washed out. Catheterisation, however, was exceedingly difficult and no improvement in the general condition took place. After a consultation Mr. Allingham performed suprapubic cystotomy on May 2nd and without much difficulty enucleated the whole prostate which weighed one and two-third ounces. There was a well-marked middle lobe which acted as a valve to the urethra. A drainage tube was placed in the suprapubic wound. On the fourth day after operation the bladder was washed out with boric lotion through a No. 7 catheter, which passed without difficulty, and this process was repeated every morning. Some urine was passed per urethram on the 9th and after this in increasing quantities. The patient got up on the 20th and was discharged on June 6th; the suprapubic wound was then soundly healed, catheters were no longer used, and the urine was acid and clear, passing freely and with some power.

CASE 3.—A healthy-looking old man, 80 years of age, was admitted into St George's Hospital on April 30th, 1903, with a portion of a catheter in his bladder. He had had enlarged prostate for 15 years and during that time had regularly passed a No. 7 gum elastic catheter for himself. On the evening of April 29th, whilst the catheter was being withdrawn, a piece about four inches long broke off and was left behind in the bladder; no pain or inconvenience resulted from this accident. On admission the urine was acid and quite clear and per rectum a greatly enlarged prostate was felt; the patient was in vigorous health, being accustomed to walk from ten to 12 miles daily. Mr. Allingham operated on May 2nd. The bladder was first distended with about 30 ounces of boric lotion and was then opened above the pubes. The portion of the catheter which had been broken off was found and removed. The prostate, which was greatly hypertrophied, was then enucleated in two portions with the right index finger, the prostatic urethra being removed at the same time. Hæmorrhage was trifling and a large drainage-tube was inserted into the suprapubic opening. The weight of the prostate was two and three-quarter ounces. The patient was rather drowsy during the week following the operation and there was slight rise of temperature; urine was secreted freely. On the 6th the drainage-tube was removed and the bladder was irrigated daily with boric lotion from this date. On the 11th the stitches were removed, all drowsiness had disappeared, and small quantities of urine were being passed through the urethra, the urine being acid and free from albumin. The patient got up on the 21st and at the present time is progressing excellently.

Remarks by MR. ALLINGHAM.—These three cases form an interesting contribution to the operative treatment of enlarged prostate. Sufficient experience has now accumulated to show that total extirpation of the gland is undoubtedly the best procedure for those cases in which the symptoms are not controlled by regular catheterisation. The pain and misery which often accompany enlargement of the prostate and the frequent difficulty in the passage of instruments are strong arguments in favour of the radical operation. Other operative measures such as vasectomy have proved to be of little value, whilst partial removal of the gland is not easier than total extirpation and its results have not been nearly so satisfactory. It seems probable, therefore, that complete removal of the gland will become the routine practice for all cases of enlarged prostate in which the symptoms are not readily controlled by palliative measures and for those cases in which the condition is definitely, though perhaps slowly, progressing. The results of this procedure are excellent, in spite of the age of the patients and of serious complications which are frequently present either locally or in other parts of the body. The technique of the operation is sufficiently explained in the description of the cases. In all these patients the entire prostate gland was removed; the hæmorrhage was trifling and very little shock resulted. In Cases 2 and 3 there was complete restoration of function, urine being retained and passed without instrumentation, whilst the pain, insomnia, and other symptoms which had existed before operation were completely relieved. In Case 1, in which death occurred four weeks after operation as the result of bronchitis, the fatal result cannot be attributed to the operation; apart from this complication the patient's progress had been quite satisfactory. Extreme age appears to be no bar to the operation, provided that the patient's general condition is good. Case 3 is an excellent illustration of this point, the patient being 80 years of age.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Sarcoma of the Pancreas associated with Pseudo-lipæmia.—Experiments on Ankylostoma Larvæ.

A MEETING of this society was held at Guy's Hospital on May 3rd, Dr. A. P. BEDDARD being in the chair.

Dr. J. FAWCETT described a case of Sarcoma of the Pancreas associated with Pseudo-lipæmia. A youth, aged 19 years, was admitted into Guy's Hospital with a severe suppurative gingivitis and he died in 24 hours. At the necropsy a general suppurative peritonitis was found for which no cause could be detected. The pancreas was infiltrated throughout with a white hard growth extending at its tail around the duodenum and into other structures. Many secondary deposits were present in the glands. The histological structure of the growth was that of a lympho-sarcoma but as to whether it originated in the pancreas, the glands, or the duodenum was somewhat doubtful. The case was called sarcoma of the pancreas since the whole organ was involved in the growth. The urine was withdrawn from the bladder after death and contained neither sugar nor diacetic acid.—The blood drawn from the right heart for purposes of bacteriological investigation separated after a short while into an upper milky layer with dark blood below. This blood condition not having been suspected during life the only blood available for further examination was that in the intracranial sinuses. The following report was made by Dr. A. E. Boycott: "The blood separated into a layer of corpuscles (about one-sixth) and a supernatant creamy layer. No change was present in the red corpuscles and there was no excess of leucocytes. The creamy layer owed its colour to a number of extremely minute particles separable with great difficulty from the fluid. They were insoluble in ether or in 1 per cent. acetic acid and on staining gave no indication that they were derived from the cellular elements of the blood." It was found that the blood contained only 0·38 per cent. of fat—i.e., no more than was present in normal plasma. In addition to the interest attaching to the nature of the growth and its situation there was the special feature of the blood condition. So-called "lipæmic" blood was usually of a pinkish colour but the term "lipæmia" had been applied to any blood which after withdrawal separated into layers the upper of which was creamy. A large number of these cases were associated with diabetes, although it had been found in other conditions, such as chronic alcoholism. That it might be due to other causes than free fat had been shown by the late Dr. C. T. Coote[1] and the name of "molecular albumen" was given to it by Dr. Coote, though it was very doubtful whether this substance alone would cause the blood to become "milky." Amongst others, Dr. W. Hale White[2] had recently reported a case in which a so-called "lipæmic" blood owed its milky character to a proteid and another substance which, though allied to fat, was not a true fat. Therefore it was clear that "lipæmia" was not a correct term to use for all cases of "milky" blood. The pathology of the condition was no more clear than it was 40 years ago but fat was not the only cause of it and diabetes was not the only disease with which it was associated. Whether the pancreas had any etiological connexion with it must be left undetermined for the present.

Dr. A. E. BOYCOTT read a paper on Ankylostoma Larvæ. He said that the eggs of ankylostoma required a free supply of oxygen for development. Development did not take place if the eggs were covered with water or were in an atmosphere of hydrogen. If air was bubbled through the water the eggs would hatch. Eggs were killed by immersion in water for ten days and by an atmosphere of hydrogen in 24 hours. The adult larvæ lived in water in the laboratory for several months. In hydrogen at 20° C. they lived for 21 days, in a vacuum for about seven days, and in carbon dioxide for six days. At 37° C., however, they did not live more than four days in hydrogen or carbon dioxide. In the intestine there was very little free gaseous oxygen. Bunge and Weinland had shown that ascaris and other worms could live anaerobically for several days. Analysis of gas collected from the small intestine of cats and rabbits showed that the percentage of oxygen varied from *nil* to about 4. Attempts to induce further development of the extra-corporeal stage of ankylostoma by keeping them with blood, duodenal mucosa, and with deficient oxygen had been uniformly unsuccessful.

LIVERPOOL MEDICAL INSTITUTION.

Strangulated Inguinal Hernia.—Partial Enterocele, Strangulated.—The Treatment when certain Foreign Bodies have been Swallowed.—Digestants.—Interpretation of Physical Signs in Pleural Empyema.

A MEETING of this society was held on April 28th, Dr. JAMES BARR, the President, being in the chair.

Mr. K. W. MONSARRAT related a case of Strangulated Inguinal Hernia with an unusual complication. The patient was a man, aged 45 years, and the hernia was operated upon 24 hours after the onset of the symptoms of strangulation. The gut was intensely congested but except for a greyish purple patch on the entering coil at the neck of the sac it did not show evidence of marked damage. At the end of the following week the patient complained of vague general abdominal pain and this was accompanied by evening pyrexia. The pain became localised to the right iliac fossa and during the seventh week after operation symptoms of chronic intestinal obstruction commenced. The abdomen was opened in the right iliac region and a mass of coiled small intestine was found bound to the parietal peritoneum by a dense adhesion and there were numerous other adhesions between the coils, one of which was causing a *definite compression. The adhesions were divided*, the omentum was used to cover some of the raw surface, and the abdomen was closed. This operation was followed by subsidence of all morbid symptoms.

---

[1] THE LANCET, Sept. 8th, 1860, p. 232.

[2] THE LANCET, Oct. 10th, 1903, p. 1007.

Mr. T. O. LITLER JONES related a case of Richter's Hernia in a woman, 73 years of age, who was admitted into the Liverpool Royal Infirmary with a history of four days' pain and abdominal discomfort with slight distension and a small lump in the right femoral region. There was no constipation or vomiting, neither was there a history of hernia. A strangulated femoral hernia being diagnosed, operation was proceeded with. The gut was adherent to the sac which contained foul-smelling fluid; the protrusion was of about the size of a half-inch marble, of an ashy grey colour, too far gone for recovery. The constriction being divided, the gut was gently pulled down and the diverticulum was invaginated into the lumen of the bowel. Lembert's sutures of fine silk were used to secure the peritoneum. The sac was removed, the wound was washed with an antiseptic, a small drain was used, deep sutures to attempt a radical cure were now inserted, and the patient was put back to bed. An uninterrupted recovery followed, the patient leaving the hospital in the fifth week. This was the second case that had come under his care, the other requiring enterectomy and being in the inguinal region. The bud-like process in the latter case was about half the lumen of the bowel; 14 inches were removed. The patient was a man, aged 48 years, and also made a good recovery.

Dr. W. BLAIR BELL read a note on a method of treatment which he had adopted in two cases in which children, aged 18 months and four and a half years, had swallowed foreign bodies—the one a brooch and the other a bed-knob. He had given the children absorbent cotton-wool teased finely in their food. The result had been extremely satisfactory in each case, the swallowed body being passed in at most 18 hours enveloped in the wool.—In reply to Mr. LITLER JONES Dr. BELL said that so far as he knew the method was a new one and that he could find no record of similar treatment, although "hair" had been recommended since it had a faculty for forming hair-balls.

Dr. CARTER read a note on Digestants and related a number of experiments illustrating the relative values of recent and old pepsin and of papain as digestants of proteids. He also mentioned other experiments showing the influence of antiseptics on both peptic and pancreatic digestion and the contrast between oxidising antiseptics and others. Lastly, he pointed out that the bacillus typhosus did not influence digestion and though, as a rule, antiseptics had no restraining influence on the bacillus, yet peroxide of hydrogen, lysol, and formalin in such degrees of dilution as admitted of their administration internally had a marked effect, both inhibiting the growth of, and killing, the bacillus.

Dr. R. J. M. BUCHANAN read a paper on the Interpretation of Physical Signs in Pleural Empyema. He drew attention to the frequent occurrence in cases of pleural effusion of auscultatory signs the same as those obtaining over solid lung. He considered Baccelli's sign untrustworthy as a distinction between serous and purulent effusions. The auscultatory signs over purulent effusion resembled, in his experience, those over consolidated lung more than those over serous effusion and he offered an explanation in support of his view, based upon a series of illustrative cases. He was of opinion that serous effusion exercised a selective rather than a wholly inhibitive influence over the transmission of vocal vibrations. He pointed out the danger of errors in diagnosis in cases of the "acute pneumonic type" of pleuritis and the probability that in such cases purulent effusion might be present from the onset. In concluding Dr. Buchanan emphasised the necessity for a more careful study and interpretation of the physical signs so as to establish strong grounds in practice for advocating exploratory puncture.—Dr. A. G. GULLAN mentioned a case in which the vocal fremitus, breath sounds, and vocal resonance were transmitted through a purulent effusion. The patient was a man, aged about 40 years, who was supposed to have a thickened pleura, as he had a previous history of pleurisy on the affected side. His temperature, night sweats, and general appearance were considered by the physician in charge to be due to large tuberculous cavities which existed at both apices. After death, however, the upper parts of the lungs were affected by marked tuberculosis but pus was found in the pleural cavity.—Dr. T. R. GLYNN mentioned the importance of the obliquity of the line of dulness in pneumonia when the patient was sitting up. He said that in some cases, though the clinical symptoms pointed to a large effusion being present, only a small quantity of fluid could be drawn off, the excessive dulness being due to concurrent pneumonia.—Dr. W. B. WARRINGTON said he thought the existence of bronchial breathing was independent of the nature of the material conducting the glottic sound and was observed equally whether the fluid was serous or purulent. He considered the chief difficulty was to explain the existence of bronchial breathing in some cases of pleural effusion and in others the diminution of all the normal auscultatory phenomena.—Dr. HUBERT ARMSTRONG remarked that empyema, like enteric fever, was a disease which occurred with greatest frequency in children and yet was generally discussed in the aspects which it presented in adults. A most important point in the diagnosis was the altered position of the apex beat. This and the extreme dulness with distinctive resistance on percussion were the signs on which he placed most reliance, but when in doubt he never hesitated to explore, using a large needle.—Dr. E. T. DAVIES said that in his experience the most trustworthy sign of pleural effusion was the absence of vocal fremitus, but the only certain evidence of pleural effusion was obtained by the use of the exploring needle.—The following gentlemen also took part in the discussion: Dr. NATHAN RAW, Mr. LITLER JONES, Dr. JOHN HAY, Dr. J. HILL ABRAM, and Dr. J. LLOYD ROBERTS.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on April 15th, Dr. W. J. Sinclair (Manchester), the President, being in the chair.—The meeting was devoted to a discussion on Abortion. Dr. W. E. Fothergill (Manchester) brought forward some points regarding the Pathology of "Habitual" and Incomplete Abortion. "Habitual" abortion was defined as a term applied to the consecutive occurrence of from three to five abortions in the same patient without any sign of syphilis. He had examined a large number of specimens from such cases and had found that *there was constantly present* thrombosis of the intervillous spaces to an extent sufficient to cause death of the ovum. Regarding the use of chlorate of potassium in such cases, he asked whether the drug diminished the coagulability of the blood. Speaking on incomplete abortion with reference to the fate of portions of ovuline tissue left in the uterus in non-septic cases, he said that, of course, in many instances breaking down and discharge of the tissue occurred but in others he suggested that the decidual cell acted in some degree as a phagocyte, eating up the ovuline tissues. He further suggested, on the ground of microscopical observation, that the decidual cell was an active phagocyte with the function of repelling invasion by chorionic villi. When the decidual cells failed to check the activity of the fœtal villous growth deciduoma malignum *might result*.—Dr. J. B. Hellier (Leeds) introduced the Medical Indications for Induction. To establish an imperative indication, the patient's life must be seriously threatened and the operation must be likely to do good. In advanced cardiac disease induction in the early months of pregnancy was hardly ever the correct treatment and strong reasons were adduced against the performance of the operation in cases of pulmonary tuberculosis and of insanity. On the other hand, Dr. Hellier recognised its value in three classes of diseases: 1. Hyperemesis gravidarum of the "pernicious" kind, in which early induction was necessary to obtain a successful result. A pulse of 120 implied a serious condition; one of from 130 to 140 meant a doubtful prognosis in any case. Women who before conception had had symptoms of gastric ulcer, although the symptoms might have ceased for some time, were liable to suffer severely from vomiting in pregnancy. 2 Certain cases of chorea gravidarum in which serious nervous and constitutional symptoms appeared. 3. Cases of albuminuria and anasarca due to nephritis. When the toxæmia was due to the pregnant state the termination of the latter led to cessation of the production of the toxic material. But this effect was not instantaneous, time was required before improvement could be obtained, and therefore induction must not be delayed too long.—Dr. J. E. Gemmell (Liverpool) brought forward the Methods of Induction. Bearing in mind the hæmorrhage and sepsis arising from incomplete natural abortion, the method chosen should be that in which these complications were best guarded against. The time selected should therefore be before the end of the fourth month; the method, that of dilatation by means of Hegar's dilators, curettage, and gauze packing, after the same preparations and under the same conditions that were usual in any other surgical operation by the vaginal route. By this method the whole field of operation was under control from beginning to end; the difficulty of extraction of the fœtus was overcome by the use of ovum forceps, or if necessary by removing the fœtus piecemeal. Dr. Gemmell's experience was of six cases in 18 years: 1. At the third month: use of sponge tents, finger and ovum forceps. 2 At third month: gum elastic bougie and gauze packing of the vagina; expulsion in 24 hours; sequelæ: pelvic cellulitis and abscess. 3. At the third month, for cancer of the cervix: bougie, expelled in 24 hours; the introduction of a second was followed by expulsion of the ovum 48 hours later. 4. At the second month: for hæmophilia which had led to nearly fatal post-partum hæmorrhage at each of three previous labours; passage of the sound and separation of the membranes; expulsion at the end of 36 hours. 5 and 6. Dilatation and curettage at one sitting. If pregnancy be allowed to advance to the fifth month induction was of doubtful value to the patient. If it be necessary the method of dilatation followed by gauze packing or the smaller Champetier de Ribes's bag was the safest line of treatment.—Dr. W. Walter (Manchester) introduced the Treatment of Incomplete Abortion, dealing with both the non-septic and septic states.—Dr. W. Macfie Campbell (Liverpool) introduced the Treatment of Abortion. After briefly reviewing the prophylactic measures Dr. Campbell said that the treatment of threatened abortion was simple and unsatisfactory, although he had occasionally been surprised by the good results from ergot which had been given to empty the uterus. With inevitable abortion arose the question as to whether treatment should be expectant or active. The first required time, carried a constantly increasing risk of sepsis, and had depressing effects upon the patient's mental state. There were also the possibilities of retention of portions of placental tissue and the need for subsequent interference. In active treatment, if tamponnement of the vagina did not lead to the emptying of the uterus, he preferred dilatation followed by digital or instrumental clearing out. He had found digital removal a difficult procedure unless the ovum was almost extruded and therefore he preferred to use the ovum forceps. With care and gentleness the pain was trifling and extraction was generally easy. If the finger discovered some attached tissues he employed Donald's flushing curette. Bleeding sometimes went on after removal or curetting and it was then necessary to pack the uterine cavity.—Dr. D. Lloyd Roberts (Manchester) held that "habitual" abortion was due to syphilis. He advocated early abortion in cases of serious cardiac disease, in nephritis, and especially in hyperemesis in which he had never regretted the performance of the operation.—Dr. A. Donald (Manchester) considered induction to be justifiable in cases of moral insanity. He carried out the induction at one sitting, dilating up to No. 16 (Matthews Duncan) and then using the flushing curette. Recovery followed without a bad symptom —Dr. J. M. H. Martin (Blackburn) thought that "habitual" abortion was due chiefly to malpositions of the uterus or to neurotic conditions. In hyperemesis it was absolutely wrong to abstain from intervention.—Dr. E. O. Croft (Leeds) took a middle position in regard to induction. He advocated preliminary treatment by instrumental separation of the ovum or by packing the cervix with gauze. As a result the cervix became softer and was more easily dilated subsequently. Surgical methods, he thought, were advisable only in urgent cases.—Dr. E. T. Davies (Liverpool) supported Dr. Donald's remarks anent moral insanity on the ground of a similar case in his practice.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on April 27th, Dr. J. Nigel Stark, the President, being in the chair.—Dr. Robert Jardine read notes of a case of Recurring Eclampsia. The history of the first attack was as follows. A married woman, aged 30 years, a quartipara, was admitted into hospital under Dr. M. Black's care on April 23rd, 1903. She was believed to be eight months pregnant. She had three fits before admission and was unconscious when admitted. There was slight œdema of her hands and feet and her urine was loaded with albumin. Under treatment she regained consciousness on April 26th and was delivered by natural efforts on the following day of a dead child. There was still a trace of albumin in the urine when she left the hospital. On Dec. 3rd the patient was again admitted to the hospital in a semi-comatose condition with a history of convulsions which had continued for 12 hours. The urine was found to contain a large quantity of albumin with granular and hyaline casts and degenerated blood cells. Saline solution was injected subcutaneously. The os uteri was dilated with Bossi's dilator and a live child was delivered with forceps. The tube casts disappeared but there was still a trace of albumin when the patient left the hospital.—Dr. Jardine also read notes of a case of Hydrocephalus with Post-partum Hæmorrhage. The patient, who was a married woman, a bipara, was admitted to hospital on Oct. 12th, 1902, after two attempts had been made to deliver her with forceps outside. The uterus was firmly moulded round the child but there was no special thinning of the lower uterine segment. The uterus was in a state of continuous tonic contraction. The large head could be felt to crackle under the fingers. Dr. Jardine perforated and delivered by means of a cranioclast As profuse hæmorrhage came on he cleared out the placenta and compressed the uterus bimanually. An intra-uterine douche at 120° F. was given, followed by a solution of suprarenal gland, 30 grains to the pint. As the uterus still remained uncontracted it was plugged with iodoform gauze.—Dr. J. K. Kelly read notes of two cases of Primary Carcinoma of the Ovary. In each both ovaries were affected. One patient was married and 45 years of age and the other was unmarried and 30 years of age.—Dr. Peter McBryde showed a Long Feather which was discharged from a labial abscess in a girl, aged 15 years.—Dr. S. J. Cameron showed a case of Spina Bifida in which operation was performed on the day of birth. The skin over the tumour had been injured during parturition and showed a tendency to slough a few hours after birth.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 19th, Dr. H. Angus, the President, being in the chair.—Mr. Vaughan Bateson gave an address on Medical Customs of the Tibetans, which was illustrated by photographs and specimens of charms, &c. He said that the medical men were priests and that drugs were very little used in the treatment of disease but that they relied chiefly on charms. These were in some cases objects of the nature of jewellery or in others inscriptions on paper which were worn on the person, different inscriptions being used according to the object desired. Other remedial measures were bathing in waters which at certain times were supposed to possess healing virtues, and the use of musical instruments, drums and trumpets. Surgical measures were apparently never undertaken among the Tibetans. In cases of snake-bite pieces of sandstone were applied to suck away the poison. Syphilis, at least in the familiar form, was rare. Leprosy was common, as was apoplexy. The methods of disposing of the dead were described. Cremation was practised in the case of persons of peculiar sanctity but was rare owing to the scarcity of fuel. The most common practice was to expose the body to be eaten by vultures and wild animals. Bodies were also put into the water sometimes.—Questions were asked by Dr. D. Goyder, Dr. H. J. Campbell, Dr. W. A. Evans, and Dr. S. Johnston, and Mr. Bateson replied.

ASSOCIATION OF ASYLUM WORKERS.—The annual meeting of this association will be held at the Medical Society's House, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, May 17th, at 4 P.M., when Sir James Crichton-Browne (President of the association) will be in the chair. All interested in asylum work and workers are cordially invited to attend.

Reviews and Notices of Books.

Nothnagel's Encyclopædia of Practical Medicine: Diseases of the Liver, Pancreas, and Suprarenal Capsules. By LEOPOLD OSER, M.D., EDMUND NEUSSER, M.D., HEINRICH QUINCKE, M D., and G. HOPPE SEYLER, M.D. Authorised translation from the German. Edited, with additions, by REGINALD H. FITZ, M D., and FREDERICK A. PACKARD, M.D. London, Philadelphia, and New York: W. B Saunders and Co. 1903. Pp. 918. Price, cloth 21*s.* net; half morocco, 25*s.* net.

THIS volume forms an excellent work of reference on diseases of the organs dealt with and especially from the pathological and clinical standpoints. The first section deals with Diseases of the Pancreas and comprises some 300 pages of which over 30 are devoted to a very complete bibliography of the subject. It is the work of Dr. L. Oser of Vienna and is prefaced by a short article on the anatomy of the pancreas by Professor Emil Zuckerkandl and one on the physiology of the organ by Dr. Katz who is also responsible with Dr. Oser for many of the experimental researches of which protocols are given in the text. A critical statement and exhaustive discussion of the general pathology, symptomatology, and treatment of pancreatic diseases follow. The groups of symptoms found in pancreatic diseases in general are most carefully recorded and impartially considered with reference to their significance and value in diagnosis. These symptoms Dr. Oser divides into three groups: the first, those directly referable to the impaired action of the pancreas, comprising glycosuria, diabetes, fatty stools, and faulty digestion of proteids; the second includes symptoms which are in many cases suggestive but by no means pathognomonic, such as urinary changes other than glycosuria, sialorrhœa pancreatica, an early and rapidly advancing cachexia, and the so-called bronzed diabetes; and the third group comprises symptoms which do not by themselves suggest pancreatic involvement—namely, jaundice, pain, and dyspeptic symptoms. The remainder of the section is devoted to the separate consideration of the individual diseases of the pancreas. Among these we may mention as very excellent and complete the accounts given of the various forms of pancreatitis and the relation of hæmorrhagic processes to them, of cysts and cancer of the pancreas, and the discussion of the nature and origin of fat necrosis. A commendable feature is the frankness with which Dr. Oser points out the incomplete character of our present knowledge of many matters concerned and the difficulty, in some cases the impossibility, of forming a diagnosis with the means at our disposal, while his plea for careful observation and record of cases of pancreatic disease in general we can heartily endorse. It is also gratifying to recognise that the labours of English and American workers on the subject are duly recognised. Dr. Fitz, the editor of this section, whose own work on pancreatic disease is so well known, has added many editorial notes of great value, bringing the work more up to date, although, of course, many advances have been made since the publication, notably the recent work of Mr. A. W. Mayo Robson and Dr. P. J. Cammidge (THE LANCET, March 19th, 1904, pp. 773, 782, &c.).

The second section deals with Diseases of the Suprarenal Capsules and is the work of Dr. Edmund Neusser of Vienna. Its general plan is similar to that of the preceding section, though as a whole it is less critical and less well arranged, and it is considerably improved by the additions of the editor, Dr. Fitz, notably in the case of the therapeutical uses of suprarenal extract. The account of Addison's disease is, however, a valuable and exhaustive review of our knowledge of it. Dr. Neusser endeavours to combine the internal secretion and the auto-intoxication theories of the function of the suprarenals; the pigmentation in Addison's disease he regards as a secondary phenomenon not dependent on the capsular disease but on the associated involvement of the abdominal sympathetic system.

The third section, that dealing with Diseases of the Liver, occupies more than half of the book. It is the joint work of Dr. Quincke and Dr. Hoppe-Seyler of Kiel and like the other two sections begins with an anatomical and physiological introduction followed by a general account of the pathology and symptoms of hepatic disease, after which the individual diseases are considered separately. The bibliography here, however, is given for each disease and not collectively at the end of the section. The general accounts are, of course, of a less controversial character than in the previous sections and are almost without exception clear and critical. In the section on cholelithiasis great stress is laid on the rôle of micro-organisms and the catarrhal processes produced by them in the genesis of gall-stones. In that on cirrhosis the author (Dr. Quincke) perhaps hardly does justice to the work of English observers, while the account of malignant disease of the liver is not quite so clear as could be wished. Hydatid disease is very carefully described and an excellent discussion of the nature of multilocular or alveolar hydatid disease is appended to it. This section was edited by Dr. Frederick A. Packard whose untimely death is deplored by the general editor, Dr. Alfred Stengel, in his preface.

Annual Report of the Public Health of Gibraltar for the Year 1903 By W. H. HORROCKS, M B, B Sc. Lond, D.P.H. R.C.P.S. Eng, Major, R.A.M.C., M.O.H. Gibraltar: Garrison Library Printing Establishment. 1904. Pp. 22.

Major Horrocks points out that in order to compare the death-rate of Gibraltar with the death-rates shown in the Registrar-General's latest return it is necessary to calculate a "standard death-rate." The population of Gibraltar, as compared with that of England and Wales, has a proportionately small number living at the ages of high mortality and a proportionately large number at the ages of low mortality. Consequently, the general death rate as recorded is too favourable and must be corrected for age and sex distribution in order to make it comparable with the corrected death-rates given by the Registrar General. The general death-rate of 17·62 per 1000 is low, the mortality being highest in the first quarter and lowest in the third quarter of the year. The infantile mortality of 179·6 per 1000 is very high and considerably above the average, the high rate being due to a large number of deaths from bronchitis and broncho-pneumonia. Among the diseases causing mortality enteric fever proved fatal in five out of 20 reported cases. The principal zymotic diseases caused 49 deaths, equivalent to a zymotic mortality of 2·11 per 1000 of the total civil population. There were 31 deaths from tuberculous diseases, equivalent to a death-rate of 1·52 per 1000 of the total civil population. Major Horrocks details the administrative measures which are necessary in the struggle against tuberculosis. He writes that the general sanitary condition of Gibraltar is satisfactory taking into consideration the overcrowding of individuals in houses and the aggregation of houses on areas which characterises the town. House-to-house inspection continues and month by month insanitary houses are brought into line with modern requirements. The by-laws as to drains and sanitary fittings require to be brought up to the standard. The supply of drinking water has been a source of anxiety owing to the deficient rainfall. During the year a collecting area of ten acres has been provided on the sand slopes above Catalan Bay. This area is capable of yielding 240,000 gallons per inch of rainfall. The sand has been covered with corrugated iron sheets laid on creasoted timber framing. The water from the area is collected in a channel at the bottom of the slope and is conveyed to four reservoirs.

A collecting area of 37 acres is projected and an increase to the reservoirs which will allow of a pipe supply to individual houses. At present the distribution of drinking water by butts and barrels is mainly in the hands of private individuals. A scheme has been elaborated by which all butts and barrels are sterilised by steam once a week. Should an epidemic of enteric fever or cholera occur it will be feasible to sterilise all the butts and barrels once a day. The bacteriological laboratory has been completely equipped and it is now possible to make a systematic biological examination of the public water-supplies. The supply of sanitary water to the high-level districts near Moorish Castle has been improved by the construction of a high-level reservoir. The ventilation of the main sewers, a matter of great difficulty, is under consideration. For the removal of refuse the commissioners have decided to replace the straw baskets by covered galvanised-iron receptacles. It is hoped that the sanitary commissioners will soon be able to erect one of the new destructors at the North Front. All infected articles of clothing and bedding have been satisfactorily disinfected in the Washington Lyon disinfecting apparatus. The dairies and cowsheds in the town are not satisfactory. Major Horrocks is anxious that the Dairies, Cowsheds, and Milkshops Orders of the Local Government Board shall be made to apply to Gibraltar. Constant supervision has been exercised over the food-supplies sold in the town. The report is evidently one of sterling work.

A Manual of Pathology. By JOSEPH COATS, M.D. Glasg., late Professor of Pathology in the University of Glasgow. Fifth Edition, revised throughout by L. R. SUTHERLAND, M.B. Glasg., Professor of Pathology in the University of St. Andrews. With 729 illustrations and two coloured plates. London, New York, and Bombay: Longmans, Green, and Co. 1903. Pp. 1287. Price 28*s.*

IN reviewing a text-book so well known as "A Manual of Pathology" by the late Dr. Coats no words are required to explain the scope and character of the publication. The fifth edition has been admirably revised throughout by Professor Sutherland and the work may be regarded as one of the best treatises on the subject of pathology. The requirements of the student have been kept prominently in view and the whole manner in which the manual is written is particularly adapted to the purpose of conveying a sound knowledge of pathological processes; at the same time the practitioner will find the work a valuable one for reference.

Much interesting material is contained in the first section of Part I., headed Nature, Causation, and Terminations of Disease in General. The chapter on bacteriology has been omitted, as Professor Sutherland rightly considers that this subject is now one which can only be adequately dealt with in special works. The etiological connexion of bacteria with disease is, however, referred to and we are glad to find that due emphasis is laid on the variation of the powers of resistance to the inroads of pathogenic organisms on the part of the tissues as being an important element in the causation of pathological conditions. With the advance of knowledge in bacteriology there has been a great tendency to magnify the powers of the seed and to forget the influence of the soil. The actual etiology of particular forms of disease is in many cases obscure because of the limitations of medical knowledge. The most obvious manner in which morbid changes may be set up is by the direct interference of forces external to the body but equally important is a pre-existing condition which renders certain structures more liable to interference than others. This pre-existing state may be inherent in the actual structure of the part or it may be an acquired peculiarity, and this "susceptibility" or "predisposition" cannot be too strongly impressed upon the student when studying pathogenic factors. In this connexion the remarks on exposure to cold are interesting. It is pointed out that exposure can scarcely be the direct cause of disease as it produces in different persons most diverse results. It is probable, however, that the effect of the exposure is, by reflex nervous influences, to render some part unduly susceptible to the exciting cause of disease, the locality which is thus rendered susceptible being determined often by the individual characteristics of the person attacked.

In our review of the previous edition[1] we drew attention to the brevity with which the developments of hæmatology were considered. In the present edition this defect has been fully remedied and a good account is given of the Alterations of the Blood and its Constituents.' The description of the various forms of leucocytes is particularly lucid and the introduction of two coloured plates considerably adds to the value of the letterpress. The condition of leukæmia receives due attention and the various tissue changes found in connexion with the disease are carefully noted. The microscopic changes occurring in the blood in cases of malaria are also described and directions are given as to the technique employed in the examination of the blood for the hæmatozoon.

The method in which the pathology of the various systems and organs of the body is discussed deserves high praise. A noteworthy feature of the book is its thoroughness; there is no "padding" with unnecessary details of conflicting theories, yet nothing that is of importance seems to be omitted. Some text-books on pathology are only guides to morbid anatomy but Dr. Coats's manual is not so limited. Not only are the structural alterations brought about by disease described but the essential nature and (so far as present knowledge permits) the individual causes of morbid processes are minutely investigated. The student is thus introduced to the scientific study of disease in as broad a sense as possible and the knowledge so attained will be of incalculable value to him subsequently when engaged in the actual practice of his profession. The book is well illustrated and the fact that in this edition the number of illustrations has been increased from 490 to 729 is proof of the complete manner in which the work has been revised.

The Prevention of Consumption. By ALFRED P. HILLIER, M.D. Edin., Secretary to the National Association for the Prevention of Tuberculosis. London: Longmans, Green, and Co. 1903. Pp. 225. Price 5*s.* net.

THIS little book, which comprises 157 pages of large text together with illustrations and an appendix of 68 pages embracing reprints of articles by the author and others, forms yet another addition to the already numerous books and pamphlets upon the same subject. In this instance the book has had the advantage of being revised by Professor Koch and the eminent pathologist writes a few introductory remarks in which he commends the efforts of the author. Dr. Hillier has certainly been at pains to collect much heterogeneous material relative to the subject of which he treats, embodying as it does comments upon the attitude of the antivivisectionists and upon the influence of pulmonary tuberculosis upon art. The book is written at a higher level than any of the previous efforts of the author with which we are acquainted and there are indications that the reviser has modified or restrained some of Dr. Hillier's former views which were perhaps a little extravagant. One effect of this editing has been, in a sense, to enhance the value of the book but it has also introduced something like a dual authorship which rather complicates the professedly popular character of the volume. We find, for instance, that in one place the author is seeking to explain the meaning of certain recent scientific work not easily comprehended by the layman while on another page there is the homely injunction—in big print, too—"Do not spit on the floor." In explaining the nature of the disease too much space is devoted to the opinions of the ancients and too little, relatively, to modern ideas. As a popular exposition we cannot say that this little volume compares altogether favourably with Dr. S. A. Knopf's "Tuberculosis as a Disease of the Masses and how to Combat it," a popular essay which in 1901 was awarded the prize offered by the International Congress on Tuberculosis which met at Berlin in 1899. But notwithstanding this a discriminating public will derive much useful information from Dr. Hillier's book. We say "discriminating" because in some places the author has not always succeeded in conveying the meaning which we imagine that he intended to convey. For instance, his remarks on compulsory notification in Sheffield leave the impression upon the reader that the local Act subjects tuberculous persons to the same penalties as regards exposure and the like as is the case with acute infections diseases, but this is not so. So, too, with respect to prevention, the statement that "measures which count on general hygiene alone are feeble and futile" is an unfortunate one, seeing that these very measures have apparently been responsible for the enormous decline which has taken place in the disease. Certain special measures are doubtless desirable but we shall do well to resist any neglect of "general hygiene." We are glad to see that Dr. Hillier accepts the view for which we have constantly contended in our columns—i.e., that the infectivity of pulmonary tuberculosis is "undoubtedly low"—but we do not quite follow his meaning when he says that having regard to the long period during which infection may last "this low infectivity is enough under certain circumstances to hand on infection from one case to at least one or two more and thus keep our tuberculosis death-rate as it is to-day." The "certain circumstances" do not obviously obtain generally as the disease continues steadily to diminish. Another instance of over-statement occurs on p. 156, where the author remarks that "the man sent home on a sick allowance and a weekly bottle of medicine from some dispensary to spit on the hearth and cough his time away amidst the family is doomed himself and will probably infect others." Surely this should read *may possibly infect others*. If, as is by no means unlikely, a second edition of this little book is called for, Dr. Hillier will do well to modify some of the passages to which we have referred, and he might, too, with advantage devote a little more space to the results of open-air treatment. A few remarks on the possible fallacies of the statistics relating to sanatoriums would be useful, as the assumption underlying these figures that had the patients not entered the sanatoriums they would either have died or have become worse is, of course, largely gratuitous. When maps or charts relative to the distribution of pulmonary tuberculosis are furnished the author should state the year or the periods to which they relate and care should be taken to ascertain that the term "tuberculosis" has the same meaning wherever the figures relating to it are compared.

---

[1] THE LANCET, August 11th, 1900, p. 403.

The Bombay Medical and Physical Society. Vol. VII., No. 1. January, 1904. Bombay: Printed at the Times Press. 1904. Pp. 37.

AT the annual meeting of this society the report for the preceding year was read and was followed by three papers—the first, by Lieutenant-Colonel H. P. Dimmock, I.M.S., on Trypanosomiasis, in which he drew attention to "epidemic dropsy" which particularly requires investigation; the second, by Lieutenant-Colonel Collie, I.M.S., Notes on a Few Selected Operation Cases at the Petit Hospital; and the third, by Captain E. F. Gordon Tucker, I.M.S., on Plague, a Soil Infection. Colonel Collie's operation cases are of considerable clinical interest; they are cases of "pyosalpingo-oöphoritis," of "ovarian cyst with twisted pedicle," and of "enlarged spleen, much elongated pedicle allowing the spleen to occupy the right side of the abdomen; acute symptoms from twisted pedicle." In this case the abdomen was occupied by a large hard tumour on the right side extending from Poupart's ligament to the costal arch but separable from the liver. The tumour extended about two inches to the left of the middle line between the umbilicus and the pubes and on the right side into the lumbar region where its outline could be distinctly felt. It was hard, smooth, and mobile; the contour towards the middle line was well defined and presented a slight depression opposite the umbilicus. On percussion over the splenic region an area of dulness could be marked out as large as is often found with a normal spleen and on deep palpation it appeared that the spleen could be felt in its normal position. Though the tumour "felt like an enlarged spleen on the wrong side of the body," the diagnosis made lay between a sarcoma of the ovary with a twisted pedicle and a renal tumour. At the operation a large dark slate-coloured, apparently solid, tumour was found occupying the whole right side of the abdomen; it appeared at first sight to be fixed to the spine, but on raising the tumour the pedicle was found to extend as a broad twisted band into the splenic region. It was this broad band which was taken for the spleen; the tumour was the spleen displaced. On examining the pedicle a double twist was observed and in order to undo this the spleen had to be lifted out of the abdomen. Before closing the abdomen the colour of the spleen had markedly improved and its consistence was softer. The patient recovered and, when the dressings were removed, the spleen was found adherent to the abdominal wound and diminished to a sixth of its former size. The history of the case is most instructive.

Captain Tucker's paper is worth study. He dwells on the circumstance that we know little or nothing of the characteristics of the "bacillus pestis" as a saprophyte in nature. He writes: "We wish to know whether the involution forms which we can produce by methods which only in a very inadequate manner mimic the conditions under which the bacillus may flourish in external nature represent forms under which the bacillus may remain latent or non-virulent for long periods in houses, clothing, some host other than man and rodents, or the soil. Or, if it be demonstrated that in a town which has suffered from one epidemic and has remained quite free for months but again becomes the seat of the pestilence, evidence of definite infection through some imported case is always forthcoming, and that there is no such thing as plague reappearing spontaneously in a previously infected district under seasonal or other variations, then the question arises, What are the peculiar local conditions which favour the occurrence of an epidemic after definite periods of quiescence or at definite seasons of the year in a particular locality?" The problem before us is to attempt to find out the position and condition of the plague bacillus in nature during the latter portion of the "period of quiescence," when it is probable, though not proved, that it exists in the state of a facultative saprophyte. Should it be ultimately proved, as Captain Tucker ventures to think that it will be, that the plague bacillus exists as a saprophyte in the soil, it will have the result of impressing on the public that the one and only way of dealing with the problem is partial evacuation carried out on scientific lines, an evacuation of houses rigorously maintained for eight weeks against all and any who refuse to avail themselves of the protection provided for them by the Government through inoculation.

LIBRARY TABLE.

Short Talks with Young Mothers. By CHARLES GILMORE KERLEY, M.D. London and New York: G. P. Putnam's Sons, The Knickerbocker Press. 1901. Pp. 282. Price 5*s.*—We have read this little book with considerable interest. It is full of practical suggestions and has evidently been written by a man who has had wide personal experience in the management of the nursery. It is singularly free from all theoretical bias. Dr. Kerley has many interesting observations to make on the subject of habits and with reference to the question of capricious appetite—one of the commonest and most objectionable habits incidental to childhood—he recommends an original line of treatment which he claims to be followed by very excellent results. Habits of appetite, like other bad habits, are very easily engendered in young children by carelessness on the part of the nurse, and when once acquired they can only be removed by systematic attention. Habits of bed-wetting, masturbation, nail-biting, and thumb-sucking are particularly liable to manifest themselves in degenerate children born of neurotic parents and they are particularly difficult to cure. Every word that Dr. Kerley has to say on the subject of these habits is worth attention and is useful not only for mothers but for practitioners also who are frequently consulted on these matters. The directions for the feeding of infants and young children are very simple and in accordance with the best modern principles. For infants graduated mixtures prepared by the combination of gravity cream, pure milk, sugar and water are recommended. By the use of the formulæ which the author supplies an accurate percentage modification is secured without any mechanical and chemical interference with the natural properties of milk. With regard to the preservation of the milk the author is in favour of pasteurisation as opposed to sterilisation. We highly commend the diet schedules which are drawn up for children from one year to six years of age. Two points which we consider of very great importance have evidently been carefully borne in mind in drawing up these dietaries. One of them is that the diet should be thoroughly representative, varied and free from monotony, and secondly, that an adequate supply of nitrogenous food apart from butcher's meat should be provided for the requirements of tissue growth. We consider these dietaries, if intelligently modified to meet the requirements of personal idiosyncrasies and individual peculiarities of digestion, will prove of the greatest use to those who are called upon to arrange a child's diet. It is impossible in a short space to do justice to the excellence and originality of this little book. We can only advise all those who are interested in the study and rearing of children to read what Dr. Kerley modestly describes as "Short Talks with Young Mothers."

The Meal Poke, University of St. Andrews, University College, Dundee. Edited by B. BELLYSE BAILDON, M.A., Ph.D., and R. COCHRANE BUIST, M.A. St. And., M.D. Edin., for the Committee of the Students' Union Bazaar. Dundee: James P. Mathew and Co. 1903. Pp. 112.—This is a book apparently written for a bazaar. It does not possess a formal prose introduction but possibly the first verse of the opening poem may serve in some measure to suggest at least the origin of the title:—

> "The meal-pokes, the meal-pokes,
> The sonsie, gaucie meal-poke,
> Baith rich and puir are fain to gi'
> To ony students' meal-poke."

Amongst the contributors to the volume are Dr. Bellyse Baildon (the author of the prefatory verses), Dr. Arthur Balfour, Dr. R. Cochrane Buist, Dr. J. M. Barrie (who is not at his best), and Dr. Andrew Lang, whose playful humour finds a suitable outlet in his article on Andreapolis. The book contains a number of illustrations and two pieces of music, of which one, entitled the "Pawkie Duke," is stated to be "a Scottish national song for the guidance of Englishmen and other foreigners."

Mechanical Vibratory Stimulation, its Theory and Application in the Treatment of Disease. By MAURICE F. PILGRIM, M.D., First Vice-President of the American Electro-therapeutic Association, Professor of Psychiatry in the New York School of Physical Therapeutics, Editor of Department of Psychiatry in the *Journal of Advanced Therapeutics.* New York: The Lawrence Press. Pp. 152.—Dr. Maurice F. Pilgrim teaches that mechanical vibratory stimulation increases the volume of the blood and lymph flow, increases nutrition, improves the respiratory process, stimulates secretion, improves muscular metabolism, stimulates the excretory organs, relieves congestion, and inhibits pain. The great remedy, however, must be properly employed and the book is written to show how this may best be accomplished.

Burdett's Hospitals and Charities, 1904. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press. Pp. 1032. Price 5*s.* net.—This useful compilation is larger by some 12 pages than the issue for 1903. Seven pages of this increase are due to an increase in the introductory matter, this again being probably due to the space given to the affairs of St. Bartholomew's Hospital. *En passant* we wish that Sir Henry Burdett would not write about "Bart.'s" as he does upon p. 78. This slang, however, in no way detracts from the value of the information concerning hospitals with which the book is mainly concerned. Not only are hospitals in these islands dealt with but there are also accounts of Indian and colonial hospitals, of those in Egypt, and of British hospitals abroad. There is in addition a section dealing with American hospitals. We can add nothing to what we have said upon previous occasions—namely, that the book is indispensable to anyone who wishes to know about hospitals and their management.

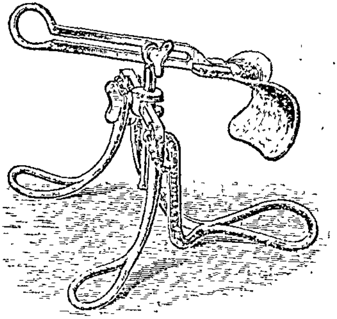
The Old Riddle and the Newest Answer. By JOHN GERARD, S.J., F.L.S. London, New York, and Bombay: Longmans, Green, and Co. 1904. Pp. 293. Price 5*s.* net.—In this work the author endeavours to demonstrate by quotations and inferences drawn from the writings of the greatest scientific men that the forces of the universe itself do not and cannot solve the great riddle which from the beginning of time nature has offered to every thinking man. The author says that the enemies of science are not the Philistines alone who would muzzle or stifle her. More numerous and dangerous are those, professedly of her own household, who ascribe to her pretensions of which she herself knows nothing and who strive to make her responsible for a philosophy entirely beyond her scope. The work is an inquiry as to how far the assumptions of scientific men are rational. That the Cosmos in which we dwell has not existed for ever is a truth enforced by the researches of physical science no less than by the clear teaching of reason. It certainly had a beginning and there must be a Cause to which that beginning was due—a cause capable of producing all which we find to have been actually produced. The material universe and the mechanism of the heavens, organic life with all its infinite marvels and varieties, animal sensation, human intelligence, the canons of beauty, the law of good and evil—all these must have existed potentially in the First Cause, as in the Source whence alone they could be derived. In particular the Law of Evolution has been studied in its various significations in order to determine from the point of view of reason and science alone whether it can be said that the prime factor is thus supplied. Darwinism is weighed and found wanting. Fleischmann's lectures, which have appeared in book form in Leipsic, are quoted which contend that "the theory of descent has not a single fact to confirm it in the realm of nature. It is not the result of scientific research but purely the product of the imagination." The author contends that it has become apparent that the days of Darwinism are numbered. He considers that the result of the investigation makes it evident that while modern discovery has immensely multiplied and magnified the marvels which have to be accounted for, it has disclosed nothing which can be supposed to account for them in a manner to satisfy our reason and our intellectual need for causality. The origin and nature of matter and force, the source of motion, of life, of sensation and consciousness, of rational intelligence and language, of free-will, of the reign of law and order to which all nature testifies—all these are for science utterly unsolved problems. Since it is not possible to find the cause required within the world of material forces and sensible phenomena it becomes no less obvious that it must lie beyond, across the frontier which nothing material can pass. We know that a Cause exists. We know that it must possess every excellence which we discover in nature, all that she has and more, since what she derives from it the Cause of nature has of itself. In it must be all power, for except as flowing from it there is no power possible. Finally, as a capable Cause of law and order in nature and of intellect and will in man, the First Cause must be super-eminently endowed with understanding and freedom in the exercise of its might or it would be inferior to its own works. Nature not being intelligent, not even a being, but an order of things constituting a power subject to law, cannot therefore be God. She is the wondrous product of an Almighty Will. And so the author says that, in the words of Rivarol, God is the explanation of the world and the world is the demonstration of God. He adds that the acceptance of a Self-existent, All-powerful, and Intelligent Being can alone serve as a basis for any system of Cosmogony which satisfies our intellectual need of causation, while, on the other hand, the nature of this Being, as necessarily beyond the scope of our senses, can be known to us only indirectly through the effects of which He is the cause. The book is written in a scholarly vein and the diction is clear but the question involved is as old as human intelligence and the volume might just as correctly have been entitled "The Old Riddle and the Oldest Answer."

New Inventions.

SELF-RETAINING ABDOMINAL RETRACTORS FOR USE IN THE HYPOGASTRIUM AND EPIGASTRIUM.

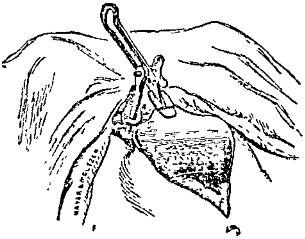
RETRACTION of the parietal incision in abdominal surgery is only necessary when the viscus or tissue under operation cannot be brought outside the abdominal cavity. On these occasions, especially when considerable force has to be exerted and maintained for some time, automatic retraction, provided that the correct angle and direction can be readily obtained, is preferable to manual, firstly, because greater steadiness can be secured, and secondly, because it partially, or entirely, takes the place of an assistant, a matter of no small moment in operations of emergency in private practice and at all times a great consideration with many surgeons on the score of asepsis. The instruments, which are represented by the accompanying illustrations, have been made for me by Messrs. Mayer and Meltzer and consist of two pieces of apparatus for automatic retraction from the direction of the pubes and sternum respectively. The former, or hypogastric set, Fig. 1, is merely a further development of Doyen's self-retaining retractor, but differs from it in that the tripod stand, which is fixed by the weight of the pelvis as well as of the thighs, allows of variation of the position of the point from which retraction is made, both laterally and vertically. The latter is most essential in that the vertical distance between the surface of the operating table and that of the mons Veneris varies greatly in spare and very stout females. The pelvic limb of the tripod is detachable to facilitate packing and is so shaped as to allow of instruments or the whole hand being introduced into the vagina. The blades, six in number, of two different depths and three different widths, are adjustable to the same handle.

FIG. 1.



Hypogastric set.

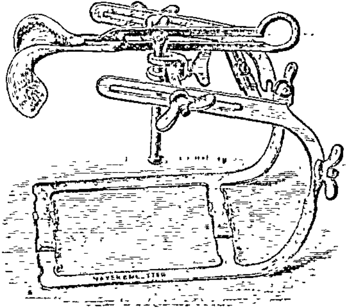
FIG. 2.



In situ.

When in position the instrument, if not required, is no inconvenience to the operator, since the handle is withdrawn towards the knees and the blade not attached. To retract a longitudinal or oblique incision in the lower half of the abdominal wall (the operator standing on the right) the selected blade is introduced with its long axis parallel to that of the wound, rotated into the

FIG. 3.



Epigastric set. The vertical pin which carries the retractor handle is erroneously shown projecting below the level of the horizontal bar. On the far side the frames are shown disconnected.

transverse position and held in the lower angle of the incision with the left hand, whilst with the right the handle is first adapted to the slot on the back of the blade and then fixed firmly to the stand in the required position by tightening the two winged screws (Fig. 2). The operation in which I have found this apparatus of most use has been hysterectomy, especially when there has been troublesome bleeding from the floor of the pelvis or where in the case of a retroperitoneal fibroma a ureter has been accidentally wounded and required suturing.

The epigastric set (Fig. 3) consists of a double frame hinged together over the shoulders and capable of being fixed at any angle by means of two winged screws, thus allowing the elevation of the horizontal bar, which carries the retractor handle, to be varied according to the depth of the chest. The position of the bar can also be varied in the slots in the sides of the anterior frame according to the length of the chest. I have found this instrument of the utmost value in operating for perforated gastric ulcer in the neighbourhood of the cardiac orifice. A deep blade is used and the upper angle of the median incision together with the liver and left costal margin forcibly retracted upwards and to the left (Fig. 4). Respiration is not affected since the anterior frame does not come in contact with the patient at all and the posterior frame is either fixed by the patient's weight or at most is only further steadied by pressure of its curved ends as they pass over the shoulders against the thick edge of the trapezius muscle. The unavoidable spring in the frame is no disadvantage, all the slack being taken up when the blade and handle are fixed. Like the hypogastric set it can be set up and placed in position in a few seconds and if not required in no way interferes with the operation as the handle is withdrawn towards the chin. It can be easily packed into an ordinary bag, the width of each frame being reducible by half for this purpose.

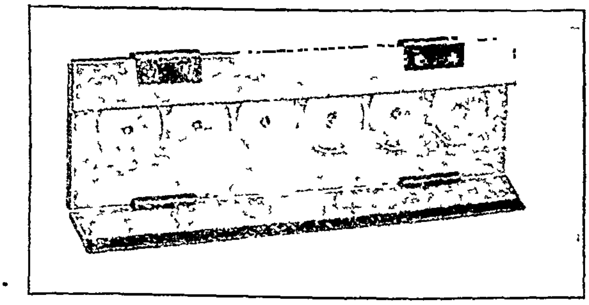
AN INSTRUMENT FOR PREPARING AND CARRYING COVER-GLASS FILMS.

This instrument consists of an aluminium case made up of a central portion with two hinged sides. The central portion contains "cells," in which the cover-glasses exactly fit, of such depth that when in position the upper surface of the cover-glass is flush with the aluminium surface. The hinged sides have a strip of indiarubber on the under surface to afford a firm hold on the cover-glass. For use, the cover-glasses are slid into the "cells," the hinged sides are turned down and held in position; a little blood is taken on the edge of a slip of visiting card or cigarette paper and lightly drawn across each cover-glass. The following are the advantages of this method which have been proved by several months' trial; it has been chiefly used for blood films but is equally good for others: 1. Saving of time at the bedside. No time is wasted choosing and picking up cover glasses. 2 Cleanliness. The cover-glasses need never be fingered. When prepared the instrument can be kept closed by an elastic band applied lengthways and wrapped in paper, contamination of the films by dust, &c., being thus avoided. 3. If films require to be fixed by heat the instrument can be placed in an oven with the films in position. 4. The films obtained by this method are more satisfactory than those obtained by the usual process of slipping cover glasses apart 5. The instrument is inexpensive and can be prepared by any good mechanic.



D. G. Marshall,
Major I.M S

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A Comitia was held on April 28th, Sir William S. Church, Bart., K.C.B., the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members of the College: James Graham Forbes, M.A., M.D. Cantab., Donald George Hall, M.A., M.D. Cantab., Charles Christopher Heywood, M.A., M.B. Cantab., L.R.C.P., George Mackay MacDonald, B.A., M.B. Cantab., L.R.C.P., David Sommerville, B A., M.D. R.U.I., and Edward Turton, M.D. Vict., L.R C P.

Licences to practise were granted to 99 gentlemen who had passed the required examinations.

A report was received from the examiners for the Murchison scholarship which was awarded to Mr. W. H. Harwood-Yarred, a student of St. Thomas's Hospital.

The following Members having been nominated by the Council were balloted for and elected as Fellows of the College: Bertram Louis Abrahams, M.B. Lond., William Cecil Bosanquet, M.D. Oxon., Thomas Robert Bradshaw, M.D. Dub., John Francis Harpin Broadbent, M.D. Oxon., Edmund Henry Colbeck, M.D. Cantab., William John Gow, M D. Lond., Arthur John Hall, M.B. Cantab., Edward Johnstone Jenkins, M.D. Oxon., Arthur Carlyle Latham, M.D. Oxon., and Charles Arthur Mercier, M.B. Lond.

The following communications were received: 1. From the Secretary of the Royal College of Surgeons of England, reporting certain proceedings of the Council on April 14th. 2 From Lady Clark, offering for the acceptance of the College a marble bust of the late Sir Andrew Clark, Bart., by H. Bain-Smith, 1888. The best thanks of the College were given to Lady Clark. 3. From the Lister Institute, inviting the College to allow its President to be nominated, *ex officio*, a Member of the Council. The request was acceded to. 4. From the Board of Trade, thanking the College for the report on beri-beri and asking permission to print it. Permission was granted.

The quarterly report, dated April 15th, of the College Finance Committee was received and adopted.

A report, dated March 21st, from the Committee of Management was received and adopted. The committee recommended the Royal Colleges to insert the following note after Paragraph xviii., Section ii., of the Regulations—viz., "Note.—A candidate who possesses a registrable qualification is admissible to re-examination without producing evidence of attendance on additional hospital practice." The committee also recommended that the Simon Langton Schools at Canterbury should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and practical chemistry.

Another report from the same committee, dated April 11th, was received and adopted. The report recommended that the St. Paul's Eye and Ear Hospital, Liverpool, should be added to the list of ophthalmic hospitals recognised by the Examining Board in England.

A report, dated March 4th, from the Laboratories Committee was received and adopted.

After some further routine business the President dissolved the Comitia.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1904.

"Passing Off."

"THE methods of commercial dishonesty are many and various and if they amount to fraud they are illegal." The quotation is from a small volume recently published,[1] the author of which, Mr. J. CUTLER, K.C., as a barrister of experience and as an authority upon the law relating to patents and trade-marks, can claim to have had considerable opportunities of appreciating mercantile ingenuity. The contents of the book were originally made public in the form of lectures delivered at King's College, where Mr. CUTLER is professor of law, and it is consequently explanatory and instructive without being rigidly technical. Its subject also is calculated to interest others than students as it will explain to those concerned with commercial morality the extent to which the law enables honest traders to protect themselves and their customers against "substitution." The protection afforded by a registered patent or trade-mark is more or less familiar to all. The intricacies which beset the administration of the law, the technical difficulties which may prevent a trade-mark from being registered or which may cause another to be removed from the register, are matters which puzzle the layman and upon which even the lawyer may speak doubtfully, but the fact that there is a register which affords valuable protection to the owner of a name or emblem distinctive of his business is generally grasped, and it is equally recognised that a distinguishing device although associated with a trader's goods in the public mind may, nevertheless, not be registrable as a trade-mark. That which is not always understood, even by those persons who have dishonest ambitions with regard to their neighbour's customers, is that even if the latter has no trade-mark, either registered or registrable, he may still have a remedy against those who seek to sell their goods as his. His action, however, in this case will be not in respect of an infringement of a trade-mark but for "*passing off*" and the claim will be that by using a copy or a colourable imitation of the mark which denotes or distinguishes the plaintiff's goods the defendant is representing that his goods are those of the plaintiff. The aggrieved party will succeed if he proves, first, that the mark on which he relies distinguishes his goods in the market and, secondly, that the mark used by the defendant is calculated to represent the defendant's goods as those of the plaintiff. It will be remembered that in the recent action brought by Messrs. BURROUGHS, WELLCOME, and Co. against a firm of druggists the claim was to restrain the defendants from passing off their goods as the goods of the plaintiff as well as for the infringement of the "tabloid" trade-mark. It was the motion of the defendants to expunge this trade-mark from the register, their failure as to this, and their subsequent appeal which made this portion of the action so prominent. The plaintiffs, however, in addition to establishing their right to their trade-mark obtained an injunction as to the "passing off," and to this they might have been held to be entitled even though the word "tabloid" had been removed from the register.

The question of "passing of" is one of interest to medical men in respect of other goods besides drugs. There are many articles for internal and external use which the medical practitioner may recommend and in respect of which he may desire to rely upon qualities associated with the wares of a particular manufacturer. In these columns we frequently give the results of our examinations of articles of diet and of other things, the makers of which no doubt profit by such praise as we are able to bestow. This may be when the manufactured article is introduced to the public, perhaps by one who hardly recognises at first the value of his production and of its scarcely acquired reputation. Later, when it has come to be associated with his name or with the distinctive label or wrapper which he has chosen for it, he will find that others are only too ready to supply the demand which he has created. These will not only offer similar goods to his, which they may have a right to do, but will copy the general "get up" and appearance of his wares by which the purchasing public know them, with the direct object of deceiving buyers who are not closely observant. Practically all the leading cases upon "passing off," the outline of which Mr. CUTLER gives in illustration of his points, have been decided at the instance of firms whose names are familiar to everybody, such as LEVER in connexion with soap; DUNLOP in connexion with the accessories of cycling; KODAK, a name which must necessarily suggest a well-known firm but which had been applied by the defendants to bicycles; and HENNESSY in connexion with brandy. Some of these cases refer to the use of a name and some to the imitation of a wrapper or label. The remedy with which Mr. CUTLER principally deals is the civil remedy, the result of which is an injunction restraining the defendant from passing off his goods as those of the successful plaintiff, together with pecuniary damages where such are due. Proceedings of a criminal nature can also be resorted to under the Merchandise Marks Acts and Mr. CUTLER discusses in his concluding chapter the relative advantages of civil or criminal process and the circumstances which justify resort to the latter branch of the law.

The work to which we have referred, it will be observed, treats only of the deceit which takes advantage of the reputation of a brother trader and for which he accordingly seeks a remedy. It is not concerned with that iniquitous form of commercial dishonesty which indirectly injures the honest trader by passing off goods by means of the pretence that they are what in fact they are not. This more public offence is dealt with penally under such statutes as the Merchandise Marks Act and the Sale of Food and Drugs Act and frequent newspaper reports of cases affecting the food rising to £600. He was allowed to do other work and held three other important appointments. He resigned in 1902. During this period no report was issued by the medical officer. The first report was issued in 1903 by Dr. James Kerr who was appointed in 1902. His salary was £800 per annum, rising to £1000, and he was not allowed to hold any other appointment. Let us give the Board credit for what it has accomplished. When it commenced work the prospect was enough to appal the most ardent lover of education. The Board was hampered by a badly drawn Act and by the fatal British love of compromise. As a Board it acted with conspicuous unfairness for years towards the medical profession and was not infrequently extravagant. But within the last few years, owing to wholesome checks administered by the result of Regina *v.* Cockerton and the refusal of the medical profession to give certificates, the Board was beginning to settle down. Of the conduct of its individual members we can say nothing but praise. They have ungrudgingly devoted their time and their talents to the service of the children of the poor and they have left the new education authority a sound system upon which to carry on the work which the School Board organised.

[1] Passing off, or Illegal Substitution of the Goods of One Trade for the Goods of another Trade, by John Cutler, M.A., K.C., Professor of Law at King's College, London, and editor of the Official Reports of Patent Design and Trade-mark Cases. London, Gay and Bird, Limited, 1904, pp. 94, price 1s. net.

MALARIA AND PREVENTIVE MEASURES.

One of our correspondents has recently had the opportunity of meeting some of the invalids from the English regiments quartered temporarily in the hinterland behind Aden during the progress of the Boundary Commission which is working under General Maitland to decide on the frontier which Turkey is to accept. It appears that the Hampshire Regiment landed in Aden in February, 1903, 1100 strong, being actually over strength. 300 men were despatched to take part in the Somaliland campaign, where there are certain obvious risks contingent on active service and a fair chance of a medal for the survivors when the fighting is all over. The rest of the regiment, all presumably in good health after service in India, were marched up to the hills where they left sandy wastes behind them and got into a hilly country where tea and coffee are grown. A few weeks ago, or about a year after the regiment landed from India, the principal medical officer held an inspection and decided that 75 per cent. of the men were unfit for duty. We understand that there have been 32 deaths in this regiment in Aden and that about half of these were due to malaria. The ordinary causes of sickness must have accounted for a few of the 75 per cent. but the great bulk of them are being invalided for malaria with the ordinary symptoms of intermittent fever, sweats and consequent debility, anæmia, and enlarged spleens. There are pools of water in this hinterland near the soldiers' camping grounds and many mosquitoes and the regiment was paraded daily for a preventive dose of quinine while a non-commissioned officer stood by to see that the men really drank the prescribed dose. But we are informed that there were no mosquito nets provided by the authorities either for officers or men and the officers naturally suffered in a similar proportion, four having been already invalided home and three now being in hospital in Aden. The fever-stricken men blanched as if from prolonged hæmorrhage, crawling about like chronic invalids, are now being sent home, and as their mission was a political one they will probably get no medal to compensate them. But we now know that malaria is a preventable disease. Why was this regiment not supplied with mosquito nets which are now served out even to black soldiers in the Soudan? If our information is incorrect we shall be glad to have it authoritatively denied but if it is correct in substance we hope that the matter will be inquired into. We have heard it whispered that in India troops in barracks even in malarial stations are not yet supplied with mosquito netting, though the hospitals are well provided with it. It is only fair to the Indian Government to state that the Dublin Fusiliers who were relieved by the Hampshire Regiment and the "Buffs" who were sent to Aden last October have both suffered less from malaria than the unfortunate Hampshires.

THE HOUSE OF COMMONS AND VENTILATION.

In an annotation which appeared in our issue of Oct. 10th, 1903, p. 1033, the substance of the report which a select committee of the House of Commons had presented in regard to the ventilation of the House was embodied. This topic has again been disturbing the equanimity of Members without, so far as we can see, any very urgent reason and the animated discussion upon it which on April 28th occupied so large a part of the valuable time of our legislative assembly does not appear to have produced any particular result. As we pointed out at the time there is really very little to find fault with in the ventilation and Mr. T. W. Russell was probably quite correct in saying that a great deal of nonsense was talked about the matter. This opinion seems to have been shared by Sir M. Foster, Sir W. Foster, and Dr. Farquharson, all of whom are well qualified to form a competent judgment on such a point. The only serious defect in the arrangements which the committee's report brought to light was that the air inlets were placed in the floor and covered by matting over which those who entered the chamber had to pass, so that particles of dust and mud from the boots of the persons concerned were introduced into the air current and so disseminated. This, of course, is by no means a satisfactory system and the sooner it is amended the better. We do not suppose that Members would take kindly to Mr. Weir's suggestion that they should leave their boots at the door, even though the assistance of "eight Japanese girls in their native costume" was available to this end, but some inexpensive structural alterations overcoming the difficulty should be quite feasible.

ATTEMPTED SUICIDE BY MEANS OF ILLUMINATING GAS.

In the *Boston Medical and Surgical Journal* of March 24th Dr. F. Holyoke has published a case of attempted suicide by means of illuminating gas which presents several points of interest. The inhabitants of a tenement house were disturbed by moaning in one of the rooms during the afternoon and evening. At 8 P.M. they knocked at the door but were not answered. The police were called in and on breaking open the door found the windows closed tightly and gas escaping from two jets. The air was unbreathable and a man, aged 44 years, was lying unconscious in an easy chair. He was removed from the room and seen by a medical man within ten minutes. He was perspiring profusely and his clothes were drenched with sweat. The pupils were dilated, the face was cyanotic, the limbs were relaxed, and the pulse was imperceptible at the wrist but a feeble cardiac impulse could be felt at the rate of 140 a minute. Respiration was very slow and gasping and the jaw had dropped. After artificial respiration the breathing became more rapid. Strychnine and nitroglycerine were injected and the pulse was restored. At 9.30 P.M. the skin was pale and cold and the limbs were rigid and convulsed. The pupils were dilated and did not respond to light. There was a naphtha-like odour from the breath which did not disappear until the fourth day. The rectal temperature was 96·8° F., the pulse was 142, and the respirations were 32 and shallow. Large mucous râles were heard over the lungs and persisted until the second day. The temperature did not become normal until the third day; then it rose steadily until the sixth day when it reached

100·6°. Consciousness was gradually regained on the night of the second day. For the next two days the patient complained of great headache and of numbness in the limbs, which latter lasted for a week. On the second day was noticed a peculiar condition of the parts on which he rested when in the chair—the shoulders, the sacrum, and the buttocks. They were thickened and brawny, bright red, hot, and tender, as though scalded. After a few days the skin became loose, leaving a large denuded surface which healed slowly. The muscles of the left leg were paretic for several weeks. There was also vaso-motor weakness of this leg: when standing was attempted the skin became turgid and purple with distended vessels. The gas was a mixture of two parts of coal gas and one part of water gas.

THE TAX UPON A CUP OF TEA AND A GLASS OF BEER.

WITH regard to the proposal of the Chancellor of the Exchequer to raise the duty on tea to 8*d.* per pound a little calculation will show that when this tax is realised the indirect duty paid upon a glass of beer will still be higher than that paid on a cup of tea. Of course, as Mr. Austen Chamberlain said, everything depends upon the lightness of the beer and the strength of the tea. The question put to him in the House of Commons was: "What is approximately the amount of indirect taxation carried by a glass of light beer and a half-pint cup of tea of moderate strength?" There is no difficulty in estimating the indirect taxation upon a glass (half-pint) of light beer, for the duty upon such beer, the wort of which does not exceed a gravity of 1055, is 8*s.* per 36 gallons, which is equivalent to one-sixth of a penny on the half-pint glass. Coming to tea we may fairly assume for the purpose of calculation that on the average one teaspoonful of tea is used for making a half-pint of tea (a breakfast-cupful) and the mean weight of one ordinary teaspoonful of tea is, we find, 40 grains. There are 7000 grains in the pound, so that the indirect taxation upon a teaspoonful of tea or upon a cup of tea made from it would be $\frac{1}{22}$*d.* In other words, the indirect taxation on 22 cups of tea would be one penny, while the taxation on six half-pint glasses of light beer would come to the same sum. The indirect taxation, therefore, is nearly four times heavier on the glass of beer than it is on the cup of tea. The taxation of strong beer is, however, proportionately heavier. The question raised is of importance and it is interesting to find that on calculation the beer-drinker pays more taxation than does the tea-drinker. Total abstainers therefore can hardly prefer the charge against the Chancellor of the Exchequer that as compared with tea-drinking beer-drinking is encouraged.

STEREOGNOSIS AS A LOCALISING FACTOR IN CEREBRAL AFFECTIONS.

THE value of stereognosis as a sign in the diagnosis of affections of the brain may now be said to be established firmly by clinical evidence of indisputable character. In the *Journal of Nervous and Mental Disease* for April Dr. William Bullard of Boston, U.S.A., states that astereognosis—the inability to recognise the character and identity of small solid objects placed in the hands—"may be caused by affections of the cerebral cortex, by subcortical lesions, or by lesions in or near the optic thalamus," and occasionally by lesions of the pons and bulb. These various points constitute the complex pathway of sensations which, proceeding from the stimulus of the object grasped and manipulated in the hand, are conducted to the cerebral cortex, and hence the exact localisation of a lesion at any one point of this pathway is not always possible to be made in the absence of certain associated signs. A clinical description of the phenomenon of astereognosis and of its tests was published three years ago in THE LANCET[1] and illustrative cases were recorded. The balance of clinical and pathological evidence which has been accumulated since then shows that lesions of the parietal area of the cortex close to the rear of the genu of the fissure of Rolando are very frequently associated with varying degrees of astereognosis. There is also strong clinical evidence that subcortical lesions in this situation may produce the same symptom. Verger has reported several cases of cortical lesions in which astereognosis was present but only one in which there was proof by operation of the site of the lesion. The case was that of a man with a hæmorrhagic clot which had destroyed a part of the brain cortex. On removal of the former after trephining (by Lannelongue of Paris) the cortex was seen to be destroyed in the region of the middle third of the Rolandic area (ascending frontal and parietal convolutions), while the subjacent white substance was softened and friable. Isolated cases have been reported of lesions in the middle part of the ascending parietal convolution and the adjacent part of the inferior parietal lobe by various observers (Raymond, Walton and Paul, Dana, Mills, and Verger) which confirm the accuracy of the localisation of the "stereognostic sense" of the hand and fingers in this region, while the now classical case of Mills and Keen has shown that a single circumscribed lesion of the corona radiata lying deeply and close to the optic thalamus may produce astereognosis as an early and prominent symptom. Dr. Bullard's own case is that of a man aged 58 years, who had been addicted to alcohol. In May, 1902, he began to suffer from numbness of the left arm and leg; his lower extremities "often felt as if they were asleep." He was often unable at night to determine the position of his legs among the bed-clothes. Six weeks later he consulted a physician who found that astereognosis of the left hand was the most prominent symptom. There was some lack of "muscular sense" in this hand but muscular power (grip on the dynamometer) was unimpaired. No Romberg's symptom of ataxia was present, though the gait was a little awkward owing to a slight "dragging" of the left foot in walking. There was marked exaggeration of the knee-jerks. He grew feeble and early in July developed optic neuritis and some degree of anæsthesia over the lower part of the face on the right side. Sensation to temperature changes, touch, and pain remain normal in both hands but marked astereognosis persisted in the left hand and on the left forearm. A diagnosis of cerebral tumour was made. The patient gradually grew worse and died about the middle of September, having in the meantime lost all power of the left arm, hand, and foot. The necropsy disclosed some degree of arterio-sclerosis and diffuse nephritis. A tumour was found deeply imbedded in the brain substance of the right cerebral hemisphere. It was ill defined externally and in places approached the cortex; internally it reached the surface of the ventricle. The structures involved by this large growth included (together with adjacent parts of the corona radiata) the subcortical radiations distributed upwards to the parietal area of stereognosis as before defined and seemed therefore to support the correctness of the doctrine of the localisation of the stereognostic function.

THE SANITARY INSTITUTE.

Dr. Robert Farquharson, M.P., vice-president of the Sanitary Institute, occupied the chair at the dinner held on May 2nd at the Hôtel Métropole, London. After the usual loyal toasts Sir R. M. Hensley, chairman of the Metropolitan Asylums Board, in proposing the toast of "The Navy, Army, and Auxiliary Forces," testified to the value of the work that had been done by the Royal Army Medical Corps. Lieutenant-Colonel R. H. Firth, R.A.M.C., in replying, said that a plan was in progress by which it was hoped a greater knowledge of elementary sanitation would be disseminated among the non-medical men in the services. Sir R. Douglas Powell, in proposing the toast of "The Houses of Parliament," referred to the sanitary condition of the House of Commons. It appeared that legislators were condemned to breathe an atmosphere which trickled through tortuous and subterranean passages and then ascended through a carpet soiled with the dust shed from the shoes of the Members of Parliament on their way to and from the lobby. He shrank from describing the vast army of microbes, aerobic and anaerobic, malignant and beneficent, classified and unclassified, said to flourish in the legislative chamber. In his opinion the Sanitary Institute ought to look into the matter. Sir Francis S. Powell, M.P., in replying to the toast, said that in the opinion of Sir Walter Foster there were good microbes and bad microbes and it was a question whether in destroying them they had not destroyed more good ones than bad. The result was, however, that the last state of the House was worse than the first. Referring to the work of the Sanitary Institute he considered that in London there had been an improvement in sanitary conditions which almost amounted to a revolution. He recognised signs in the provinces that led him to consider that the housing problem was almost solved. He advocated sanitary missionaries who should proceed from house to house instructing housewives in the elementary laws of sanitation. Sir John Ure Primrose, Lord Provost of Glasgow, proposed the toast of "The Sanitary Institute of Great Britain and the Colonies," which was replied to by the chairman, Dr. Farquharson, by Mr. Arthur H. Reid, chairman of the board of examiners for the Sanitary Institute of British South Africa, and by Mr. William Whitaker. Mr. E. W. Wallis, the secretary, received many congratulations on the success of the dinner. It may be mentioned here that one of the special features of the Health Exhibition of the Sanitary Institute at Glasgow in July next will be a municipal exhibit arranged by the different departments of the Glasgow corporation. The cleansing department proposes to arrange for, amongst other things exhibits of a model up-to-date destructor and the Globe fertiliser; the gas and electric departments will exhibit the latest developments in illumination; and the sewage departments productions from what were formerly waste products. The other departments of the corporation will also be well represented. The social and holiday aspect of the Congress has not been overlooked and excursions have been arranged to the following amongst other interesting places, Loch Lomond, the Trossachs, and the Falls of Clyde.

[1] THE LANCET, May 25th, 1901, p. 1483.

INVESTIGATIONS INTO THE CAUSATION OF SMALL-POX.

AT a meeting of the Metropolitan Asylums Board on April 30th the hospitals committee reported that it had considered an application from Dr. T. F. Ricketts, medical superintendent of Joyce Green Small-pox Hospital, requesting that authority should be given to him to carry on in conjunction with Dr. C. J. Martin, F.R.S., director of the Lister Institute of Preventive Medicine, experimental work in connexion with the causation of small-pox. Dr. Ricketts informed the committee that such authority would only imply stabling accommodation with attendance and possibly a slight increase in the expenditure usually sanctioned for hospital scientific apparatus. The recommendation gave rise to a great outburst of antivivisectionist oratory on the part of a small section of managers and amendments were moved to refer the report to the hospitals committee and also to the general purposes committee for further information. Both amendments were rejected and the recommendation of the committee was agreed to. Great indignation was expressed at the action of a member of the hospitals committee who informed his board, Hackney, of the application of Dr. Ricketts before the report with its recommendation was printed on the agenda. As a result of that information the following resolution from the Hackney board of guardians was read:—

> The guardians having been informed that the hospitals committee of the Metropolitan Asylums Board have under their consideration a proposal to obtain a licence under the Vivisection Act for Joyce Green [illegible] experiments on animals, this board hereby strong [illegible] use of a rate-supported hospital for such purp [illegible] o foregoing resolution be forwarded to the Home Secretary, the President of the Local Government Board, and the metropolitan boards of guardians, with a request to the latter that when electing managers for the Metropolitan Asylums Board they will request them to oppose any attempt to use the hospitals of the Metropolitan Asylums Board for the purposes named in the resolution.

A motion to refer the letter to the hospitals committee for consideration and report was, after a heated discussion, lost and it was decided formally to acknowledge the communication.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

Professor E. A. Minchin resumed his lectures on the Sporozoa and in his sixth lecture[1] delivered at University College, London, on April 25th, dealt with the sub-class of the myxosporidia. These belong to a class different from the rest of the sporozoa dealt with in previous lectures. The myxosporidia are neosporidia—that is, forms in which spore formation begins early in life and goes on continuously during the trophic stage. Such spore formation is not an interruption of the vegetative life of the parasite whereas in the telosporidia (the other great group of sporozoa) spore formation is the end of the trophic stage. The spores are formed in the interior of the protoplasmic body, not on the periphery as in gregarinæ, hence they are called endospores. The myxosporidia comprise four families—viz., the disporea in which the parent form gives rise to only two endospores, the polysporea which produce more than two spores, the chloromyxidea, and the myxobolidea. The trophic stage of the myxosporidia is marked by a large-sized amœboid phase and the spores produced are also relatively large. With rare exceptions the spores possess two or four polar capsules each. These forms are parasitic in fishes and cold-blooded vertebrates (amphibia) but they are rare in invertebrates and not known to occur in any warm-blooded vertebrates. The parasites in fishes were first observed by the physiologist, Johannes Müller, who named them "psorosperms." They occur in two conditions—viz., freely in the internal cavities of viscera (the gall-bladder, the urinary bladder, and the pelvis of the kidney) and as tissue parasites within the parenchyma of the bodily organs. The latter form of infection of the host is the more serious and virulent of the two. It has been traced as the cause of epidemics among fishes in Germany. Thus Doflein and Hofer have shown that certain epidemics of fish disease recently observed in Germany—e.g., among barbel in certain rivers—were due to tissue infection by a species of myxobolus. The myxobolus Lieberkühnii, a yellowish slimy-looking sporozoon, is a parasite in the pike's bladder and was met with in nearly 50 per cent. of the specimens examined by Professor Minchin. It is comparatively harmless. The trophic stage of the parasite is amœboid in form with an elongated multinuclear worm-like sinuous body composed of a finely granular ectoplasm and a densely crowded granular endoplasm containing various particles—e.g., dark brown crystalloid bodies, oil and pigment droplets, and metaplasmic granules. The ectoplasm is the region which exhibits pseudopodial movement. Myxidium reproduces itself in the winter months by a process of budding, the buds which are constricted off being multinuclear. Spore formation occurs only in the warmer months of the year (endospores). This occurs by a process of encystment, the cell protoplasm within the cyst undergoing division into six or more spores (sporoplasmic bodies), each of which undergoes further subdivision into a pair of spindle-shaped bodies provided with "stinging cells" at each pole. A two-shelled protective envelope is secreted by the parasite which is now in a condition to infect a fresh host. This infection is generally of the "casual" form—i.e., produced by accidental swallowing or eating of the fish containing the parasite. When located within the alimentary canal of the new host the gastric juices loosen the shells and the little "amœbulæ" issue forth and attach themselves to, or invade, the tissues of the host. They are also carried by the lymph stream and may thus make their way into the kidneys, skin, and eye muscles. Thus a calf fed on the spores will be speedily infected by the amœbulæ which will make their appearance in the tissues and organs mentioned. In the tissues they undergo further multiplication by fission and finally the young myxosporidia imbed themselves in the tissues where they remain as ordinary parasites (trophozoites) for a more or less prolonged period. Occasionally they may give rise to serious disease or cause death of the host.

---

[1] References to the first, second, third, fourth, and fifth lectures will be found in THE LANCET of March 12th, p. 736, and 26th, p. 889, April 2nd, p. 950, and 9th, p. 1009.

CHANGES IN THE SUPRARENAL CAPSULES IN CASES OF NEPHRITIS.

Some interesting observations on the condition of the suprarenal capsules in cases of nephritis in which during life increased pulse tension was noticed are recorded in the *Tribune Médicale*, 1904, p. 119, by Dr. Aubertin and Dr. Ambert. In these cases they have found definite changes, both on naked-eye and microscopical examination, practically without exception. Eight of such cases in all were examined, while 19 cases of other diseases were studied as controls. In three of the eight cases large adenomata were found four, five, and eight centimetres in diameter respectively; in the remaining five cases the glands as a whole were larger and heavier than the normal standard. When cut into the cortical substance was found to be increased in thickness and to contain small adenomatous nodules. Histological investigation confirmed this, showing a true hyperplasia of the cortical layers; the medullary substance, on the other hand, took no part in this overgrowth; it was, in fact, somewhat atrophic. Even in the cases where the large adenomata occurred the remainder of the cortex of each gland was hypertrophied. In seven cases of renal disease without increased pulse tension no alterations were found in the suprarenal capsules; further, in 12 cases of various acute and chronic affections without increased pulse tension suprarenal changes were only found in one case; this was a case of tuberculosis with a slight degree of fibrosis of the kidneys in which a circumscribed adenoma was found, without any other change in the structure of the organ. As a result of these observations a relation was inferred to exist between the raised tension of the pulse in such renal cases and the changes in the suprarenal bodies. The explanation which Dr. Aubertin and Dr. Ambert offer of this relation is ingenious, though, perhaps, mainly speculative. Allowing that the normal suprarenal gland produces a substance in its medullary cells which increases blood pressure, they assume that the cortex produces an antagonistic body which they regard as also a protection against the effects produced by the retained toxic products in chronic renal disease. These hypothetical toxins they suppose produce increased blood pressure on the one hand and acute or chronic uræmic symptoms on the other. The hyperplasia of the cortex of the suprarenal they regard as an attempt on the part of the organism to antagonise these toxins. These observations, if confirmed, are certainly of great interest both pathologically and clinically considered, while the explanation is practically an instance of the supposed protective action from auto-toxication, a function which on other grounds some pathologists attribute to the suprarenals.

THE HYPODERMIC INJECTION OF CALOMEL: TRIBUTE TO ITS DISCOVERER.

One of our Italian correspondents writes: "Forty years ago in the clinique of the University of Pavia calomel was for the first time employed hypodermically in the treatment of disease and the practice, now general throughout Italy, especially in syphilitic affections, has amply realised the anticipations of its author, Professor Angelo Scarenzio, director of the Clinica Dermosifilopatica in the Lombard School. On the recurrence last month of the fortieth anniversary of the discovery the medical staff of the university celebrated the occasion by presenting their colleague with a gold medal bearing on the obverse a likeness of Professor Scarenzio in profile and on the reverse the following inscription:—

VII. ID. APRIL. MDCCCLXIV.
Collegae et Sodales
Ingenium Viri et Sollertiam admirantes
Die ejus inventi anniversario
A. MDCCCCIV.

The elegance of the Latinity, due to the pen of Professor Majocchi of Bologna, has its counterpart in the artistic beauty of the medal, equal in grace and finish to the best traditions of the studio from which it comes, that of Signor Johnson of Milan. The ceremony of consigning the medal was eminently 'simpatica' (to use the expressive Italian word), all the medical staff of the Lombard School being present, together with representatives of many other cliniques, foreign as well as Italian."

MENINGITIS IN MUMPS.

Among the rare complications of mumps is meningitis. At the meeting of the Société Médicale des Hôpitaux of Paris on March 25th M. A. Chauffard and M. L. Boidin described two cases of meningitis in mumps which are important because the existence of the complication was verified by lumbar puncture. A lad, aged 17 years, was admitted to hospital on Feb. 15th, 1904, the fourth day of an attack of mumps. Both parotid regions were swollen, rosy, and œdematous. The temperature was 100·7° F. On the following days the temperature fell to normal and the right parotid diminished progressively but the left (the last attacked) still remained large. On the night of the 19th the patient slept badly and complained of headache. On the 20th the temperature was 100·4°. Careful examination of the nervous and other systems revealed no cause for the headache and pyrexia; there were no signs of orchitis. On the 21st he still complained of slight headache and insomnia. The temperature was 101·8° in the morning and 101·3° in the evening but the pulse was only 56. On the 22nd the temperature was normal and the patient had slept and felt well. From the 22nd to the 26th he progressed towards convalescence but though the temperature was normal the pulse was from 56 to 60 and the patient progressively lost weight. On the 26th the parotid swelling had almost disappeared and the pulse was 80. In the second case a man, aged 36 years, noticed on Nov. 24th that his neck was a little swollen. He had no pain and paid little attention to the condition which disappeared in two days. But on the 26th he felt acute pain in the scrotum which compelled him to remain in bed. On the 28th the pain extended to the lower abdomen and he was feverish. This condition persisted until Dec. 2nd, when he entered hospital. He was prostrated, the face was red and swollen, and the temperature was 106° F. He complained of acute pain in the scrotum. The right testicle and epididymis were much enlarged and the parotid glands were a little so. On the 3rd the temperature fell to 102° but the state of the testicle had not altered. There was no headache or other nervous symptom but the pulse was 68. On the 4th and 5th the testicle was less painful, the temperature was normal, and the pulse fell to 52. Atrophy of the testicle followed. In both cases a series of lumbar punctures were made. In the first case the puncture was first performed on the fourth day and yielded normal cerebro-spinal fluid. A second puncture, made on the ninth day (when there were headache, pyrexia, and slow pulse), yielded cloudy fluid containing numerous large lymphocytes. On the eleventh day similar but less cloudy liquid was obtained. On the nineteenth day the liquid obtained was clear but it still contained abundant lymphocytes. In the second case lumbar puncture yielded on the ninth and twelfth days clear liquid containing numerous lymphocytes. Lymphocytes in diminished numbers were found as late as the eighty-ninth day. The liquid obtained by puncture was never under pressure, fibrin was always absent, and the amount of albumin did not exceed the normal. It is to be noted that the most important signs of meningitis—rigidity of the neck, Kernig's sign, the "meningeal streak," vomiting, constipation, and ocular signs—were absent. On the other hand, there were in the first case symptoms of an attenuated form of meningitis—the relapse of the fever without any lesion to account for it, the headache sufficiently intense to cause insomnia for two nights, and the bradycardia. In the second case the supervention of orchitis rendered the diagnosis of meningitis less clear and explained the very high temperature. Perhaps headache was absent in consequence of the painful character of the orchitis. On the other hand, the bradycardia was well marked.

THE REVACCINATION BILL OF 1904.

As our readers are aware there is at present a Revaccination Bill before the House of Commons, but it is unfortunately not a Government Bill. Despite the promise which the Government gave about revaccination some years ago nothing has ever been heard of any Government Bill on the subject. This being so there is not much chance that the Bill will ever reach a second reading and all the more so as it was down for May 4th, the same day as the Southwark and Birmingham Bishoprics Bill which was bound to be fought tooth and nail by a certain section of the House. Mainly owing to the action of Mr. Bryn Roberts and Mr. Lloyd-George, who are consumed with anxiety to see the law obeyed (except indeed as regards the Education Act), the question as to whether Churchmen might spend money subscribed by themselves in supporting two Bishops was debated at such length that the Revaccination Bill never had a chance. The Imperial Vaccination League has, however, published a list of persons who support the Revaccination Bill, 1904. The list is contained in a pamphlet of 78 pages. We say nothing as to the medical men whose names are found therein, for in the eyes of opponents of the Bill medical men simply care for vaccination on account of the fees which it brings in and are notoriously biased on the subject. The manifesto, which the persons named in the list have signed, welcomes legislation "making revaccination at school age compulsory on all but the children of conscientious objectors or those who may be for a time excused on the ground of ill-health." Nearly every class of the population is represented in the list but all the signatories do not approve of the conscientious objector clause. Many large employers of labour have signed and petitions in favour of the Bill have been, or are going to be, presented to the House of Commons by the Herefordshire county council, the boroughs of Finsbury, Holborn, and the city of Westminster, the municipal corporations of Bootle, Bury, Manchester, Leamington Spa, Newcastle-upon-Tyne, St. Helens, Stoke-upon-Trent, Sunderland, and the Prescot union. We wish the Bill every success but we greatly fear that it will not attain it this year.

FESTIVAL DINNER OF THE MIDDLESEX HOSPITAL.

THE festival dinner in aid of the funds of the Middlesex Hospital and its cancer charity was held at the Whitehall Rooms, Hôtel Métropole, London, on May 3rd, the Right Hon. the Lord Mayor occupying the chair. During dinner, at which about 140 guests were present, the band of the Coldstream Guards performed an excellent programme of music by permission of Colonel A. E. Codrington. The Lord Mayor, in proposing the usual loyal toasts, referred to the generous interest taken by their Majesties the King and Queen in hospitals and charitable institutions in general and the Middlesex Hospital in particular, and in proposing the toast of "Continued Prosperity to the Middlesex Hospital" he spoke of the great demands which were made on the generosity of the charitable at the present time, three hospitals alone appealing for sums amounting together to £1,000,000. In pleading the claims of the Middlesex Hospital he referred especially to its cancer charity which has continued its excellent work for upwards of a century. He then read a letter from Lord Derby announcing a donation of £1000 to the dinner fund. The Right Hon. Lord Sandhurst, G.C.S.I., chairman of the weekly board, in replying to the toast summarised some of the improvements and advances made in the working of the hospital during the past ten years, referring to the opening of the new cancer wing with its separate organisation, to the convalescent home at Clacton, to the building of the new laundry at Hendon, to the new and commodious nursing home, and to the establishment of the clinical and cancer research laboratories and the electro therapeutical department. In paying a tribute to the work of Dr. W. S. Lazarus-Barlow, the director of the Cancer Research Laboratory, Lord Sandhurst referred to his appointment on the Cancer Research Committee of the German Government and stated that the principle of the institution was coöperation with other bodies concerned in cancer research, not competition. He concluded his reply with an appreciation of the work done by the permanent officials of the institution and then proposed the health of "The Medical Staff," coupling it with the names of Mr. Henry Morris and Dr. J. Kingston Fowler. Mr. Morris, in his reply, referred to the increased cost of surgical methods and apparatus and to the increase in conservative operations. Dr. Fowler, in replying on behalf of his medical colleagues, alluded to the necessity of the endowment of medical education and research and the importance of these as a national investment, a fact already recognised by some other nations. He further pointed out the disadvantage suffered by London schools in competition with those in the provinces where local patriotism led to endowment and general interest. The toast of "The Visitors" was proposed by Lord Grenfell of Kilvey, G.C.B., G.C.M.G., a vice president of the hospital, and responded to by Mr. J. W. Watson, Master of the

Worshipful Company of Mercers. Lord Sandhurst, in proposing the toast of "The Chairman," had the gratification of announcing that the subscriptions promised amounted to nearly £6000 and expressed the hope that this would be considerably increased before the list closed. The Lord Mayor, in replying, expressed the pleasure it gave him to preside and his gratification at the result.

THE GENERAL MEDICAL COUNCIL.

THE next session of the General Medical Council will begin on Wednesday, May 25th, at the office of the Council, 299, Oxford-street, London, W., Sir William Turner, K.C.B., the President, taking the chair at 2 P.M. In consequence of the Whitsuntide holidays the session will begin on a Wednesday instead of on the usual Tuesday.

A COURSE of ten advanced lectures on the Tracts of the Brain to be given on Wednesdays, at 5 P.M., in the Physiological Theatre of University College, London, has been commenced by Dr. W. Page May. The introductory lecture upon the Structure and Tracts of the Cord was delivered last Wednesday (May 4th). The syllabus of the remaining nine lectures is as follows: Lectures 2 and 3, Topography of the Brain Stem; Lecture 4, Motor Paths; Lecture 5, Sensory Paths; Lecture 6, Basal Ganglia, Thalamus and Corpus Striatum; Lecture 7, Cortex, Localisation, Association; Lecture 8, Cranial Nuclei and their Central Connexions; Lecture 9, Optic Nerve and its Connexions; and Lecture 10, Smell and Hearing. The lectures are open without fee to all internal students of the University of London.

AT a coroner's inquest held at Birkenhead on April 13th and 20th a verdict was returned against Mr. K. McD. O'Callaghan of culpable negligence as regarded his treatment of a woman named Alcock whom he had been called in to attend six hours after the birth of a dead and decomposed child. Mrs. Alcock died from septicæmia. The charge was heard before the magistrates on April 28th and after hearing the evidence for the prosecution the bench discharged the accused. Mr. O'Callaghan, however, still has to take his trial at the assizes on the coroner's warrant. Mrs. Alcock had been attended in her confinement by an uncertificated midwife.

THE May dinner of the Aberdeen University Club in London will be held in the Trocadéro Restaurant, Shaftesbury-avenue, London, W., on Wednesday, May 18th, at 7 30 P.M. Intending diners should communicate with Mr. J. Malcolm Bulloch or Dr. Robert J. Collie at 25, Porchester-terrace, London, W.

Dr. J. Rose Bradford will deliver the Croonian lectures at the Royal College of Physicians of London on Tuesdays and Thursdays, June 7th, 9th, 14th, and 16th, at 5 o'clock. He has taken as his subject, "Bright's Disease and its Varieties."

THE seventh annual meeting of the Childhood Society will be held at 7, St. James's-square, London, S.W., on Wednesday, May 11th, when an address on Degeneracy, Physical, Mental, and Moral, will be delivered by Dr. G. E. Shuttleworth.

A TELEGRAM from the Acting Governor of Hong-Kong received at the Colonial Office on May 3rd states that for the week ending April 30th there were 25 cases of plague and 25 deaths from the disease.

THE annual general meeting of the Medical Defence Union will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on May 26th, at 5 P.M.

THE BACTERIOLOGY OF THE THAMES, OF THE SEA, AND OF SHELL-FISH.

FIRST NOTICE.

THE importance of being able to determine accurately the precise significance of the organisms found in shell-fish and in estuarial waters cannot well be overstated. On the one hand, the absence among the public of certain diseases borne by shell-fish is at stake; and, on the other hand, the livelihood and hence in no small measure the health and well-being of a large littoral population are in the balance. Moreover, the general subject has a wide scientific interest. As we have already stated in our columns when dealing with the fourth report of the Royal Commission on Sewage Disposal, the Commissioners did not consider that the bacteriological examination either of sea water or of shell-fish, "even if carried out in a quantitative as well as a qualitative manner," could at present be recommended for the purpose of distinguishing unsafe foreshores, layings, ponds, and the like. They thought, however, that the results so far obtained showed great promise. The report upon which this conclusion was largely based has now been published in the shape of an elaborate appendix to the fourth report of the Commissioners and the author of this work is Dr. A. C. Houston.[1]

This report, if we mistake not, is destined to become a classic in bacteriological literature inasmuch as it approaches *the subject from a thoroughly unbiased and scientific stand*point and in this sense it will serve to rescue the bacteriology of estuarial waters and of shell-fish from the somewhat unsatisfactory state into which it has recently fallen by the anxiety of certain bacteriologists to generalise rather too widely from the very limited facts at their disposal. The report under review consists of a folio volume of 316 pages together with numerous charts, tables, and maps illustrating the bacterial contents of the waters examined, the biological characters of the organisms discovered, and the precise position geographically from which the several samples were procured. The term "B. coli" as used by Dr. Houston includes all gas-forming bacillus coli like organisms and the biological characters of the microbes are given in tabular form. The word "communis" in connexion with bacillus coli has been avoided by Dr. Houston for the reason that, in his view, this word, if unaccompanied by any definite statement as to the tests employed and the results obtained, is apt to be misleading, whereas if all the details with regard to the subcultures are furnished the employment of the word "communis" is unnecessary. It is therefore quite open to anyone who may wish to speak in terms of bacillus coli communis to analyse Dr. Houston's tables and to arrive at his own conclusions. This course has undoubted advantages having regard to the fact that there is apparently some difference of opinion among bacteriologists as to the precise significance of the several tests which are used by one or other bacteriologist to differentiate bacillus coli communis from bacillus coli-like organisms. As regards bacillus enteritidis sporogenes the test employed by Dr. Houston was based upon the smallest amount of the sample which yielded the "enteritidis change" in anaerobic milk cultures for spores. Section I. of the report deals with

The Condition of the River Thames at Hampton and Sunbury above the Tidal Portion of the River and above the Intakes of some of the London Water Companies.

Here the water contained from ten to under 100 bacilli coli per cubic centimetre and one spore of bacillus enteritidis in ten cubic centimetres and from these results Dr. Houston infers that the Thames at Sunbury and Hampton is composed of "extremely dilute sewage"—that is to say, sewage diluted about from 1000 to 10,000 times—and it may be added that the bacilli coli found "were rarely other than typical B. coli as freshly isolated from human fæces" Dr. Houston has obviously misgivings as to the desirability of using such water as this for drinking purposes even after filtration and he discusses the potential dangers to which London is exposed from what may be called the risks attendant upon of filtration. Some will agree with him that too much importance must not be placed upon the immunity of London from enteric fever in the past; others may think that he attaches insufficient weight to the testimony of experience. But whichever view they take they will have read a very interesting discussion.

---

[1] Vol. iii. of Fourth Report of Royal Commission on Sewage Disposal, containing reports by Dr. Houston on Bacteriological Investigations. Eyre and Spottiswoode. Price 10s. 10d.

Dr. Houston next turns his attention to the lower Thames and he tells us that the 232,000,000 gallons of effluent which are daily discharged at Barking and Crossness contain at least 100,000 bacilli coli and between 100 and 1000 spores of bacilli enteritidis per cubic centimetre, while the sludge, 50,000 tons of which are taken weekly to the Barrow Deep, contains bacilli coli in numbers varying from 1,000,000 to 10,000,000 000 per cubic centimetre and bacilli enteritidis from 10,000 to 100,000 per cubic centimetre. There was, however, one sample of sludge which was strongly alkaline and which yielded negative results as regards both organisms. Dr. Houston did well to record this anomaly as it serves to accentuate the importance of taking multiple samples of any given material before arriving at a conclusion. The river at Barking and Crossness is regarded as sewage diluted about 100 to 1000 times, but the bacilli coli collected near Crossness were less "typical" than those collected near Barking inasmuch as several samples of the former either gave no indol reaction or caused no clotting in milk, while two samples failed both as regards the indol and clot reactions. This departure from the "typical" is of interest.

When the water of the Thames at Purfleet, five miles below Crossness, was examined the results were very similar to those obtained at Barking and Crossness, but there would seem on the whole to have been a further departure from the "typical"—i.e., eight of the samples examined failed to respond both to the indol and the clot test. At Grays, which is five miles below Purfleet, the conditions were appreciably better, the number of bacilli coli per cubic centimetre being on an average over 100 but less than 1000, while the spores of bacillus enteritidis varied from one to ten per cubic centimetre, but here there appeared to be no further departure from the "typical."

The next examination was made at Mucking, ten miles below Grays, where the average number of bacilli coli per cubic centimetre was ten and that of bacillus enteritidis sporogenes usually one. As regards these results Dr. Houston remarks that the Thames at Mucking was on a basis of bacteriological findings as suitable for waterworks purposes as it is at Sunbury or Hampton. This is a somewhat remarkable result and it shows how overdrawn have been some of the pictures relative to the condition of the lower Thames and the pollution of its foreshores.

At the Chapman lighthouse, five miles lower down than Mucking, although excremental bacteria could still be detected the results are regarded by Dr. Houston as very satisfactory. Here, however, the ratio of the bacillus coli-like microbes to the spores of the bacillus enteritidis became altered and in certain of the samples the spores of this latter organism were more numerous than the bacillus coli-like organisms. Seemingly the more delicate bacilli coli perish, while the resistant spores are able to survive.

The Condition of the Water in Barrow Deep.

Numerous allegations have been made with regard to the disastrous consequences of depositing the London sludge in this locality, and the whole mouth of the Thames, together with the Whitstable oyster fisheries, have been regarded as having been poisoned thereby. It is therefore eminently instructive to turn to Dr. Houston's report and to hear what is the testimony of the bacteriologist upon the subject. It may be noted in passing that the entrance to the Barrow Deep is about 13 miles seawards of the Nore and 48 miles from Crossness and it may be well to remind the reader that the 50,000 tons of sludge which are deposited weekly in the Barrow Deep contain from 1,000,000 to 10,000 000.000 bacilli coli per cubic centimetre and from 10,000 to 100 000 spores of bacillus enteritidis in the same amount. Dr. Houston's samples were apparently collected near the surface and they yielded bacilli coli from none in 10 cubic centimetres to 10 per cubic centimetre, while about half the samples gave a positive result with bacillus enteritidis sporogenes in one cubic centimetre of the water. Dr. Houston accounts for these remarkable results by supposing that the microbes sink gradually to the bottom and there undergo dissolution. But be the explanation what it may, it is impossible not to agree with Dr. Houston when he says "the results of the bacteriological analysis do not substantiate the alleged *gross* pollution of the Thames estuary and the Essex and Kentish coasts (east of a line connecting the Chapman lightship with Stoke) due to the discharge of chemically treated sewage into the Thames at Barking and Crossness and sludge into the Barrow Deep. On the contrary, the results appear to indicate that outside the Barrow Deep and beyond the Chapman lighthouse the excremental bacteria derived from the sludge and effluents respectively must be present in such small proportion in the sea water as, practically speaking, to be almost if not quite negligible. The statements which have been made to the contrary appear to have been based on conjecture." It would be instructive to compare these results with the examination of samples taken in Barrow Deep some distance below the surface and at the bottom of the sea.

Dr. Houston deals next with—

The Bacteriological Examination of the London Filtered Water,

as the Commission desired to obtain some results in this direction for purposes of comparison. Samples of water were taken from the *mains* of the East London and Southwark and Vauxhall companies and the results are, as usual, arranged in tabular form in the report. As, however, time and opportunity did not allow this matter to be gone into at all fully Dr. Houston advises that provisional inferences only should be drawn from the results. As regards the bacillus enteritidis sporogenes only one out of all the samples examined yielded a positive result with ten cubic centimetres of the water, but the results as regards the bacillus coli are regarded as the reverse of satisfactory, although many of the bacillus coli-like organisms were not completely typical of the bacillus coli. But, notwithstanding this, altogether typical bacilli coli were found in 1, 10, or 100 cubic centimetres of the water.

Dr. Houston points out that the bacillus coli is an index of excremental but not of specific pollution; he, however, conceives that "a fortuitous chain of circumstances might convert a potential into an actual and menacing danger to health." He pictures to himself the simultaneous existence of an epidemic of enteric fever in the towns of the valley of the Thames above the intakes and a breakdown of the filters. Were this to occur the result might undoubtedly be serious or even disastrous. But Dr. Houston is nothing if he is not absolutely fair and he adds, as if anxious to tone down the impression which he has produced, "it is not desirable to push unduly the question of *potential* danger to health," and after pointing out that filtration must be regarded as a relative rather than an absolute safeguard, he observes that the results which he has obtained "might fairly be used as an argument against condemning water owing to the mere presence of B. coli or gas-forming bacillus coli-like microbes, as has been the practice in the past to a large extent irrespective of their relative abundance in the samples, seeing that in this instance water was being drunk without obvious detriment to health which uniformly contained B. coli or bacillus coli-like microbes in 100, in 10, and sometimes even in 1 c.c."

With this quotation we must terminate our first notice of this highly interesting volume. In our second and concluding notice we shall draw attention to Dr. Houston's experiments as to the fate of the bacillus pyocyaneus when introduced with sewage into certain biological purification processes and to his bacteriological examinations of unfiltered sea water and of water and oysters obtained from certain localities on the littoral.

MEDICINE AND THE LAW.

The Substitution of Fish Oil for Cod-liver Oil.

At Southwark police-court a herbalist named Lardent was fined £1 with £10 10*s.* costs under the Sale of Food and Drugs Act for selling, to the prejudice of the purchaser, "cod-liver oil" which was shown by analysis to contain at least 90 per cent. of fish oil. Evidence was given of the serious aspect of such substitution in the case of so useful and widely used an article as cod-liver oil, taking into account the not only useless but detrimental qualities of fish oil. For the defence it was urged that both the defendant and the wholesale firm who had supplied him had purchased the oil as cod-liver oil, and a representative of the wholesale firm gave evidence in corroboration of this. It was pointed out in the course of the case that the bottle containing the stuff bore the inscription "Pure Selected Cod-liver Oil." The wholesale value of cod-liver oil was given as 15*s.* 2*d.* per gallon and that of fish oil as 2*s.* 2*d.* The large profit which can be realised by successful fraudulent dealing in such an article shows that those purchasing it wholesale would do well to ascertain personally the nature of what they buy and not to put implicit faith in guarantees of quality without demanding that they have been founded upon analysis. To rely upon such guarantees for a defence when other persons have made the analysis is scarcely prudent, even if the merchant only consults his own interest and disregards that of the public. The public, no doubt, regard a printed label of "Pure Selected Cod-liver Oil" as a guarantee and are not likely to be protected by any vigilance or science exerted on their behalf by the "herbalist," but substantial penalties inflicted in cases of the nature of that described may have some effect in relegating the sale of such goods as cod-liver oil to druggists who are the proper persons to deal in them.

METROPOLITAN STREET AMBULANCE ASSOCIATION.

A GENERAL meeting of the Metropolitan Street Ambulance Association was held at 20, Hanover-square, London, W., on May 2nd, the chairman being Mr. REGINALD HARRISON who in his opening remarks said that the Metropolitan Street Ambulance Association had been founded in January, 1904, by some members of the medical profession practising in London, who appointed a president and council to initiate its proceedings. The objects of the association were to endeavour to secure for London, with as little delay as possible, an efficient street ambulance service for accidents and medical casualties and, further, to promote the movement generally in various ways. That action had been taken not with any idea of undervaluing or supplanting efforts that had been made by persons and bodies to promote and to provide ambulance work, but, on the contrary, the association had all along recognised the importance of the voluntary work that had been done, particularly by the St. John Ambulance Association, and by Mr. H. L. Bischoffsheim, in addition to the first-aid services rendered by the Metropolitan and City police. The association, however, felt that the influence of a large and united body of the medical profession, practically acquainted by daily observation with existing ambulance services for the streets and holding definite views as to how these might be improved, was likely to afford valuable assistance to the authorities of the metropolis and the country in bringing arrangements relative to that important subject to a definite issue. Within a short time after its formation more than 1000 members of the profession, engaged in hospital and private practice, had joined the association on those broad lines and they were met together for the purpose of giving effect to the programme thus announced and so warmly responded to. If further testimony in support of the objects of the association was required it would be found in the words of Sir E. C. Perry of Guy's Hospital, in his report to the London County Council, "That it was very painful to watch the arrival of accidents at hospitals under the present system," and also in the statement of Sir W. J. Collins, chairman of the ambulance subcommittee, in his prefatory note to the same report, "That nearly 70 per cent. of the casualties at present conveyed to hospitals by some vehicle or other are taken in cabs and carts and not in ambulances." On that latter basis it had been calculated that from 8000 to 10,000 severe accidents were taken to London hospitals and elsewhere annually in cabs or other unsuitable conveyances. It had to be remembered that those figures mainly represented persons constituting a large mass of the population—artisans and labourers—who were the most liable by reason of their occupations to sudden accidents: those, in fact, who were least able to provide against emergencies of that kind and who, along with their families and dependents, suffered the more when thus overtaken and especially when, from lack of proper attention at the time of the accident, their recovery and wage-earning power were unnecessarily delayed. On the other hand, it was not to be forgotten entirely that the well-to-do citizen of Greater London might in like manner be suddenly struck down and rendered unconscious in the street and thus have cause to remember with gratitude the preservation of his life or limb by the timely arrival of a well equipped ambulance at the moment when the bystanders were wondering who he was and where he came from. The present state of the London streets by the large addition of "motor" and tram traffic was not calculated to lessen those liabilities. Relative to those statements he would say that about 1881, in connexion with the movement which resulted in the introduction of hand ambulances and subsequently of horse ambulances into Liverpool, he had made some extended observations as to what really happened to persons who "were brought to hospitals in cabs and carts and not in ambulances." He (Mr. Harrison) was at that time resident surgeon, and subsequently visiting surgeon, to one of the largest hospitals in that city which received annually many hundred accidents from the docks, city, and suburbs. He found that a large proportion of the fractures involving limbs which were originally simple had been rendered compound by improper methods, or the absence of methods, of removal to hospital, and, further, that where the injury or medical casualty had been attended with much shock, such, for instance, as in concussions caused by falls down a ship's hold or from aloft, in cases of severe burns and scalds, or by apoplectic, cardiac, and other seizures by which persons were suddenly rendered more or less unconscious, the conveying of them in cabs or carts in a sitting position had been not infrequently followed by speedy death after their arrival at the hospital. The deaths of patients on their way to the hospital and within 24 hours after admission were often associated with that mode of conveyance. Thus an unnecessary loss of both limb and life could be accounted for. The almost entire absence of provision of horse or motor ambulances for street accidents in London also called for comment. Without those conveyances no system for a large city could be regarded as even approaching a state of efficiency. The number of horse ambulances required for the metropolitan area could not at present be determined and must be the result of experience. New York, with its population of over three and a half million people, seemed efficiently worked with about 56 of those conveyances. Though a proportion of street accidents in the immediate vicinity of hospitals were dealt with by hand ambulances or litters which were often used for other police purposes there could be no doubt that they compared unfavourably with the horse or motor conveyance which was a necessity when the distance to the hospital was greater. Minutes, not to speak of seconds, were of the first importance, relative to antiseptic treatment, when a wound was present. Women who had met with accidents or other casualties in the streets had often complained very bitterly of their recollections of the hand ambulance and their transit along crowded streets, though under the protection of the police. Contrast that with their unobserved removal in a comfortable and smooth-running horse ambulance with a trained attendant by their side. The street ambulance service of London at the present time might be said to be carried on partly by the police, as representing what was generally known as "first aid," and partly by volunteer efforts. Whether a much divided authority was desirable, which that arrangement implied, without any guarantee for the continuance of efforts which were purely voluntary, was a matter deserving consideration. Whatever conclusion might be arrived at in reference to that point it was obvious that the time had come when a central or undivided authority which could bring into unison the various constituent parts of an ambulance had become a necessity so far as London was concerned. The constituent parts of an ambulance included the police as "first aid" on the spot, the telephone, the conveyance and its motor power, the hospital or ambulance depôt, and, if necessary, the skilled medical attendant with some appliances, all capable of concerted action for one object with as little delay as possible. When London could secure those conditions there would be no difficulty in providing it with an efficient and complete ambulance service. The chairman then called upon the secretary to state what steps had already been taken.

Dr. ARTHUR W. JAMES, the honorary secretary, said that the late London County Council had done much to forward the ambulance movement by the appointment of a subcommittee, under the chairmanship of Sir William Collins, and had issued a very valuable report in 1902. In consequence, it had been suggested, of the apparent indifference of the public no further steps had been taken in the matter. In those circumstances the Metropolitan Street Ambulance Association had been formed in order to secure the sympathy of all candidates for election to the new council and to interest the electors in a subject which so closely concerned every individual in the community. 110 medical men were appointed to act in the 58 constituencies as local honorary secretaries and these and their friends worked with great success everywhere. Letters explaining the objects of the association were sent to all the candidates with post-cards for reply asking each, "If elected to the London County Council will you interest yourselves in securing the establishment by the Council of an efficient street ambulance service for London?" Favourable answers were received in almost every case, the few exceptions being afterwards found chiefly among the unsuccessful contestants. Of the 118 newly elected councillors more than 104 were well disposed towards the movement and most of them knew that they could rely on the support in that matter of their constituents as well as of practically the whole medical profession in the metropolis. Many of those representatives were grateful for the manner in which that association brought the subject forward, as it was well known that no public body could establish an ambulance service in London without first obtaining the sanction of Parliament. It appeared to be recognised generally that the community as a whole was responsible for caring for, and properly removing, those cases of accident and sudden illness which became helpless in the public streets, though there was still some difference of opinion as to which representative body should undertake the necessary provision and administration. Their association was confident that the London County Council would accomplish that work better than any other central or local governing body, because of its representative constitution and because it appeared to have ready at hand such an efficient emergency service as the fire brigade. That brigade, with its 90 stations and resourceful staff of 1350 men, already possessed almost all the administrative machinery necessary and seemed to need little more than the addition of the required ambulances, horses, and men to make it an ideal ambulance service also. That addition of more men, especially in the smaller stations, would in all probability contribute greatly to the efficiency of the brigade, since just as firemen were now instructed in first aid work, so those primarily employed in the ambulance service could be practised in fire-drill and the two staffs made to a great extent interchangeable. In that manner both those emergency services would be mutually helpful, more efficient in consequence, and considerably more economical for London than any other arrangement. It was worthy of note that in Liverpool, which had the best street ambulance service in England and where the police, the fire brigade, and the ambulance services were all under one management and worked together, the fire brigade machinery had been utilised for ambulance purposes The drivers of the fire-engines were the drivers of the ambulances and the fire-alarm posts had been used for ambulance calls without any inconvenience. Those points, which appeared worthy of consideration, induced the council of their association to make the following suggestions as the possible basis of a plan for providing London with an efficient street ambulance service. 1. That there should be one controlling authority responsible for a uniform and well-organised ambulance service and that the London County Council, as the central representative body for the metropolis, was the one best fitted to undertake the work. 2. That London should be divided into districts or "accident areas" and a properly organised ambulance service arranged in each. This would necessitate the establishment of horse or motor as well as hand ambulances. 3 That the fire brigade and the ambulance services could be most advantageously carried out conjointly. 4 That it was desirable that some of the ambulances under the control of the London County Council fire brigade should be stationed at, or in immediate connexion with, the principal London hospitals. 5. That the police should be kept efficient in first-aid training and should be available, as at present, for rendering first aid to the injured, for summoning an ambulance, and for taking charge of the patient until the ambulance and attendant arrived, but should not necessarily be expected to accompany a patient to home or hospital. 6. That the 1000 fire-alarm telephone posts now existing and all other telephones should, if possible, be made available for calling the ambulances and the police should be instructed in their use. 7. That the experience gained in working such services for many years in New York, New Orleans, Chicago, Sydney, Copenhagen, Vienna, Paris, Liverpool, Bootle, Birkenhead, Manchester, Newcastle, Huddersfield, Bolton, Burnley, Hull, Sheffield, Leeds, and Wolverhampton was more than sufficient to justify the London County Council in undertaking the work in the metropolis on a scale large enough to provide adequately for the 13,000 to 15,000 street casualties requiring removal each year. 8. That there should be no charge for the use of the ambulance.

Dr. F. W. COCK said that from his experience of about 1000 ambulance calls at a New York hospital he was of opinion that in many surgical and medical cases much harm might have resulted if the patients had been brought to the hospital in the haphazard manner adopted in London. From 35 to 40 per cent. of the calls were for medical cases, the remainder being surgical. The ambulance was in the charge of hospital authorities but it had to be remembered that in New York the hospitals were more widely distributed than in London. In New York they were accustomed to see a medical man accompanying the ambulance but he did not think that that was necessary in London.

Sir WILLIAM S. CHURCH, President of the Royal College of Physicians of London, then proposed the following motion:

> That this association, having considered the present condition of ambulance provision in London for dealing with cases of accident and sudden illness in the streets and public places, is of opinion that there is urgent need of organisation under one body of an improved ambulance service, summonable by telephone, and provided with more rapid transport.

He said that there was great need for improvement in London of the ambulance provision for dealing with cases of accident and sudden illness in the streets and public places. The metropolis in this matter was behind many of the larger provincial towns of England. The association did not propose to initiate any scheme of its own but sought to combine the existing agencies so that they should act harmoniously and under central control. It was considered that the fire brigade was the best body with which an ambulance service should be united for the reason that such a scheme would be the most economical to adopt. Speaking as a physician he knew from experience that the present system by which many of the patients were brought to the hospitals in cabs did not in a great number of the cases give them the best chance of recovery.

Mr. TIMOTHY HOLMES, consulting surgeon to St. George's Hospital, in seconding the motion, agreed with the necessity for an improved ambulance service for the numerous accidents and cases of sudden illness that occurred in the streets of London. Under the present condition of things they must try to arrange for the conveyance of cases of accident or sudden illness to the hospitals as safely and as quickly as possible.

The motion was then put to the meeting and carried unanimously.

Mr. JOHN TWEEDY, President of the Royal College of Surgeons of England, then proposed the following motion:—

> That, having regard to the excellent ambulance services organised by municipal authorities elsewhere, this meeting is of opinion that the London County Council is the body by which such service should be provided and maintained.

He said that there was no body so competent as the London County Council to undertake the scheme. The London County Council was not unfavourable to the proposal and it was incumbent on those present to take care that public indifference should not be allowed to continue. The sympathy of the public must be stimulated and the medical profession must give expression to a united opinion that some improved system was necessary. There was no intention to dictate to the London County Council but the suggestion was made that the fire brigade seemed to be the best organisation to carry on the work, because it would provide the material and the *personnel* required for the efficient performance of the duties which would devolve on the ambulance service which they desired to see in London.

Sir ALFRED COOPER, Vice-President of the Royal College of Surgeons of England, seconded the motion which was then put to the meeting and carried unanimously.

Sir THOMAS BARLOW, physician to His Majesty's Household, then proposed the following motion:—

to the London
this association
t of other repro-

He said that it must be evident to everyone that the ambulance service should be in the hands of a central official body with the power of levying taxes so that they could see that the work was properly done. Excellent as the various voluntary bodies were that interested themselves in the matter it was obvious that they were not adequate to discharge the important and vital duties that lay before them. The London County Council was the right body to undertake the duty and the medical profession should render every assistance to the London County Council. Any sanitary work that the London County Council had taken up had been well done and in his opinion the Council would perform its duty in regard to the ambulance service in a proper manner.

Mr. W. THORBURN (Manchester) said that in his town the ambulance service was entrusted to the City Council and the details were arranged by the Watch Committee which combined some of the functions of the police and the fire brigade. The fire brigade found the horses and the police force found the men. The improved ambulance service had been of the utmost value and had been the means of saving much misery and suffering.

Mr. G. H. MAKINS, surgeon to St. Thomas's Hospital and late consulting surgeon to the South African Field Force, in formally seconding the motion, said that it rested with the medical profession to impress on the public the importance of the movement which the association had at heart. The ambulance service was an emergency service and so also was the fire brigade and if the two could be worked on the lines suggested there was no doubt that it would result in great advantage to the public.

The motion was then put to the meeting and was carried unanimously.

Sir DYCE DUCKWORTH moved, and Mr. JOHN H. MORGAN seconded, a hearty vote of thanks to Mr. Reginald Harrison for presiding, which was passed with acclamation and this vote having received a suitable response the meeting terminated.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 6, 1826.

The fact that certain vegetable substances produced an enlargement of the pupil was long ago observed, even so far back as the time of Pliny, who mentions the circumstance, and ascribes that effect to the anagallis. He says "Pupillas dilatat; ideoque solent inungi, quibus fit paracentesis."

From this observation it would appear, that the needle operation for cataract as at present performed is similar to what it was in his day. It was not, however, until the year 1799, when Himly, who is now Professor of Physic at the University of Gottingen, published a tract on the "paralysis of the iris, produced by the application of hyoscyamus to the eye," that the practice was known generally, and he is entitled to the merit of having drawn the attention of the profession to the subject. Whether hyoscyamus is preferable or not is doubtful; its influence on the iris is less powerful and more temporary, than that of the belladonna. It is however, recommended in Himly's tract, and generally used by the Germans, who are afraid of the more powerful belladonna, fancying that it injures the retina. Himly's tract was published in the French at Altona, under the title "De la paralysie de l'iris." You will find a good account of the circumstances connected with this subject, historical as well as practical, in the 11th vol. of the Edinburgh Medical and Surgical Journal, by Mr. Wishart. Himly has the merit of first seeing and clearly explaining the practical utility of this artificial dilatation, in various states of the eye. It is so important in internal inflammations, by preventing contraction of the aperture; in the distinction of cataract from other affections; in discriminating the several species of cataract; in facilitating some of our operations; in contractions of the pupil; and in many cases of leucoma, that this discovery of Professor Himly may be deemed an important epoch in ophthalmic surgery.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8844 births and 4785 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had been 18 4, 17·6, and 16·0 per 1000 in the three preceding weeks, rose again last week to 16·3 per 1000. In London the death-rate was 15·6 per 1000, while it averaged 16·7 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·5 in Reading, 8·3 in Willesden, 8·7 in Handsworth (Staffs.), 9·4 in Hastings, 9·7 in Ipswich and in Halifax, 9·8 in Walthamstow, and 9·9 in Leyton; while the highest rates were 20·8 in Wigan, 20·9 in Warrington, 21·0 in Plymouth, 21·8 in Liverpool, 21·9 in Coventry, 22·0 in Stockton-on-Tees, 22·7 in Middlesbrough, and 25·9 in Wallasey. The 4785 deaths in these towns last week included 527 which were referred to the principal infectious diseases, against 583, 530, and 556 in the three preceding weeks; of these 527 deaths 213 resulted from whooping-cough, 155 from measles, 49 from diphtheria, 41 from diarrhœa, 40 from scarlet fever, 21 from "fever" (principally enteric), and eight from small-pox. No death from any of these diseases was registered last week in Hastings, Reading, Northampton, West Bromwich, Smethwick, Grimsby, Preston, or York, while the highest death-rates from the principal infectious diseases were recorded in Hornsey, Great Yarmouth, Walsal, Birmingham, Wallasey, Warrington, Salford, and Stocton-on-Tees. The greatest proportional mortality from measles occurred in Hornsey, Brighton, Norwich, Wallasey, Manchester, Burnley, Rotherham, and Rhondda; from scarlet fever in Warrington; from diphtheria in Hanley and Barrow-in-Furness; and from whooping-cough in Great Yarmouth, Walsall, Birmingham, Warrington, Bolton, Salford, Blackburn, and Stockton-on-Tees. The mortality from "fever" and from diarrhœa showed no marked excess in any of the 76 large towns. Of the eight fatal cases of small-pox in registered in these towns last week three belonged to London, two to Halifax, and one each to Manchester, Newcastle-on-Tyne, and Tynemouth. The number of small-pox cases remaining under treatment in the Metropolitan Asylums hospitals, which had been 134, 144, and 123 on the three preceding Saturdays, had further declined to 104 on Saturday last, April 30th; 12 new cases were admitted during last week, against 25, 37, and 23 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1541, against 1505, 1523, and 1543 at the end of the three preceding weeks; 185 new cases were admitted during the week, against 141, 172, and 210 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 333, 295, and 254 in the three preceding weeks, further fell last week to 224 and were 60 below the number in the corresponding period of last year. The causes of 65, or 1·3 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Leeds, Hull, Newcastle-on-Tyne, and in 45 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, St. Helens, Manchester, Rochdale, Burnley, Halifax, Sunderland, Gateshead, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·3, 20·9, and 21·0 per 1000 in the three preceding weeks, declined again to 20 0 per 1000 during the week ending April 30th but was 3·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. Among these Scotch towns the death-rates ranged from 15 6 in Leith and 17·2 in Greenock to 22·3 in Paisley and 24·2 in Dundee. The 663 deaths in these towns included 22 from whooping cough, 19 from measles,

---

[1] Excerpt from lecture on the Anatomy, Physiology and Diseases of the Eye, by Mr. Lawrence, delivered at the London Ophthalmic Infirmary, Moorfields.

13 from diarrhœa, seven from diphtheria, four from "fever," three from small-pox, and three from scarlet fever. In all, 71 deaths resulted from these principal infectious diseases last week, against 57, 65, and 79 in the three preceding weeks. These 71 deaths were equal to an annual rate of 2·1 per 1000, which was 0·3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The deaths from whooping-cough, which had been 19, 20, and 29 in the three preceding weeks, decreased again to 22 last week and included six in Edinburgh, six in Aberdeen, five in Glasgow, and five in Dundee. The fatal cases of measles, which had been 14, 21, and 26 in the three preceding weeks, declined again last week to 19, of which ten were registered in Glasgow, three in Paisley, two in Dundee, and two in Greenock. The fatal cases of diarrhœa, which had been seven, 15, and 11 in the three preceding weeks, rose again to 13 last week and included eight in Glasgow and two in Dundee. The seven deaths from diphtheria were six in excess of the number in each of the two preceding weeks, and included five in Glasgow. The fatal cases of "fever," which had been three, four, and five in the three preceding weeks, declined again last week to four, of which two occurred in Glasgow. The three deaths from small-pox corresponded with the number in each of the two preceding weeks and were all registered in Glasgow. The fatal cases of scarlet fever, which had been two, one and four in the three preceding weeks, declined again last week to three, and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 138, 152, and 115 in the three preceding weeks, rose again to 121 last week, but were slightly below the number in the corresponding period of last year. The causes of 24, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29 7, 24 4, and 23·3 per 1000 in the three preceding weeks, further declined last week to 20·8 per 1000. During the past four weeks the death-rate has averaged 24·6 per 1000, the rates during the same period being 16 7 in London and 18·4 in Edinburgh. The 151 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 18 from the number in the preceding week and included eight which were referred to the principal infectious diseases, against 19, 17, and ten in the three preceding weeks; of these, three resulted from whooping-cough, two from measles, one from diphtheria, one from "fever," and one from diarrhœa, but not any from small-pox or from scarlet fever. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·7 in London and 1·4 in Edinburgh. The fatal cases of whooping cough, which had been eight, 11, and five in the three preceding weeks, further declined last week to three. The deaths from measles, which had been four, four, and three in the three preceding weeks, decreased to two last week. The 151 deaths in Dublin last week included 27 among children under one year of age and 40 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Three inquest cases and two deaths from violence were registered, and 51, or more than a third, of the deaths occurred in public institutions. The causes of two, or 1·3 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Deputy Inspector-General of Hospitals and Fleets Evelyn Richard Hugh Pollard has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated March 7th, 1904).

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Gerald Burton Brown has been placed on the Retired List (dated April 27th, 1904).

The following appointments are notified:—Fleet Surgeons: W. E. Bennett to the *Wild Swan* on commissioning; J. M. Rogers to the *President* for three months' hospital course; J. L. Thomas to the *Good Hope* and R. Miller to the *Rupert* and to the *Terror* on recommissioning. Staff Surgeon A. E. Kelsey to the *Andromache.* Surgeons: J. O'Hea to the *Ariadne* for the *Columbine* on recommissioning; E. R. Grazebrook to the *President*, additional for three months' hospital course; and A. F. Fleming to Chatham Yard, lent temporarily.

2nd Life Guards: Surgeon-Lieutenant R. M. Cowie to be Surgeon-Captain (dated April 11th, 1904).

Royal Horse Guards: Captain St. J. B. Killery, from the Royal Army Medical Corps, to be Surgeon-Captain (dated May 4th, 1904).

ROYAL ARMY MEDICAL CORPS.

Surgeon-Lieutenant-Colonel G. S. Robinson, Scots Guards, assumes charge of the troops and Station Hospital, Eastbourne, vice Lieutenant Colonel J. E. Fannin. Major R. E. Kelly (retired pay) on relief of his present duties by Lieutenant-Colonel P. B. Tuthill (retired pay) will be temporarily employed as medical officer in charge of the 3rd Battalion Royal Sussex Regiment during the annual training at Arundel.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant G. F. Whyte to be Surgeon-Captain (dated April 17th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Sussex: Harold Harris E Scatliff to be Surgeon-Lieutenant (dated Jan. 23rd, 1904). 1st Banff: Surgeon-Major (Surgeon-Lieutenant-Colonel, Army Medical Reserve of Officers) W. L. Stewart resigns his commission with permission to retain his rank and to wear the prescribed uniform (dated April 30th, 1904); John Hector Stephen to be Surgeon-Lieutenant (dated April 30th, 1904). 1st Cinque Ports: Surgeon-Lieutenant W. L. Chubb resigns his commission and is granted the honorory rank of Surgeon-Captain, with permission to wear the prescribed uniform (dated April 30th, 1904). 1st Devonshire: Surgeon-Captain G. P. Barton resigns his commission (dated April 30th, 1904). 1st Durham: Surgeon-Captain D. Todd to be Surgeon-Major (dated April 30th, 1904).

Royal Engineers (Volunteers): 1st Aberdeenshire: Surgeon-Captain W. Sinclair to be Surgeon-Major (dated April 30th, 1904).

Rifle: The Cambridge University: Surgeon-Captain J. Griffiths to be Surgeon-Major (dated April 30th, 1904). 3rd Volunteer Battalion the Welsh Regiment: David Hepburn, late Major, Edinburgh Company, Royal Army Medical Corps (Volunteers), to be Surgeon-Major (dated April 30th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

1st Lothian Bearer Company: Lieutenant A. A. Ross to be Captain (dated April 30th, 1904).

ROYAL JERSEY MILITIA.

The undermentioned Supernumerary Officers are absorbed into the Establishment:—*1st or West Battalion:* Royal Jersey Light Infantry: Surgeon-Major W. Falla (dated April 8th, 1904). *2nd or East Battalion:* Royal Jersey Light Infantry: Surgeon Captain F. N. Gaudin (dated April 8th, 1904). *3rd or South Battalion:* Royal Jersey Light Infantry: Surgeon-Major A. B. Voisin (dated April 8th, 1904).

THE WAR IN THE FAR EAST.

Everyone is following with extreme interest the course of events in the Russo-Japanese war which up to the present time is very favourable to the Japanese. The latest news from the Far East leaves no doubt of the nature of their success upon the Yalu, where the general staff of the Japanese army has achieved one of the most difficult and brilliant exploits in military history in crossing a river in the face of an opposing force and in successfully attacking and carrying the strongly defended positions held by the Russians. This success on land, following those on the part of the Japanese navy at sea, furnishes unmistakeable evidence of the nature and quality of the Mikado's forces. The relatively small losses on the part of both the Russian and Japanese armies in the late battles on the Yalu were a matter of surprise considering the numbers engaged, the nature of the fighting, and the military strength of the positions captured. But those on the side of the Russians turn out to have been much larger than originally reported and they seem to have principally occurred after they had given way and were in retreat. Turning, however, from these military considerations to those of a medical nature we may say that the Japanese are a most painstaking and up-to-date people in all their arrangements. They have excellent army hospitals and a good medical system and organisation. Lieutenant-Colonel W. G. Macpherson, C.M.G., of the R.A.M.C., a very competent officer, has been attached to the Japanese army to report on the medical arrangements.

In the preliminary report of the chief surgeon of the first Japanese army corps, referring to the recent operations on the Yalu, it is stated that there were 798 killed and wounded.

The Warsaw *Dnevnik*, discussing the importance of pure water for the soldiers, says the Lyao-che is a notoriously dirty river the water of which is simply of chocolate colour.

The Principal of the Russian Red Cross Society in the Maritime Province of Far Eastern Russia, Prince B. A. Vacilovitch, has advised the executive committee that the 2525 beds put at his disposition are not nearly enough. In view of this and to provide the necessary accommodation the committee proposes to fit up a number of buildings as hospitals to be ready at the end of autumn, when the war is expected to be at its height.

Besides the 63 medical men already sent to the seat of war from the Imperial Military Medical Academy a selection is about to be made from those still in the Academy of five surgeons and 12 assistants who will be specially detailed for duty for the hospital trains.

RUSSIAN LADY DOCTORS' ENTERPRISE.

On April 24th the Moscow "accoucheur gynæcological building" of the Women's Medical Institute was consecrated. This building, which has already cost 133,000 roubles (£13,300), collected with considerable difficulty in Moscow, is still incomplete as to its fittings and furniture and the task is still ahead of the Moscow branch to gather another 23,000 roubles to complete the equipment and to put the institution into working order. The house will contain 50 beds.

A YEOMANRY MASONIC LODGE.

A lodge of Freemasons in connexion with the Middlesex Yeomanry was consecrated under the name of the Middlesex Yeomanry Lodge at Freemasons' Hall by Sir Edward Letchworth, Grand Secretary, assisted by other Grand Officers on April 18th. This is the first Masonic lodge formed in connexion with the Yeomanry and its first Worshipful Master is Major W. Duncan, M.D., F.R.C.S., obstetric physician to Middlesex Hospital.

DENTISTRY IN THE RUSSIAN ARMY.

A committee appointed by the Russian Imperial Medical Academy to report on a better system of education in dentistry has concluded as follows: That the inclusion of dentistry in the Academy's curriculum is indispensable and will fill a blank in the education of military medical men. If need be new accommodation should be built and fixed remuneration for professorship should be provided, since at present such instruction in dentistry as is provided in the Academy is by a *privat-docent* without fixed fees.

THE CHOLERA AND ENTERIC FEVER EPIDEMICS AT HAMBURG.

To the Editors of THE LANCET.

SIRS,—I appreciate the honour you conferred upon me in writing a leading article on my paper about enteric fever and cholera at Hamburg and calling the attention of your readers to the facts contained therein. I am sorry to learn from your *exposé* that our opinions about the epidemiology of both diseases differ widely, yet I trust you will agree with me that not a prolonged discussion will be able to clear our theories but only the experiences derived from the next invasion of cholera in Europe. Nevertheless, I beg your permission to correct some statements of yours. You say Altona or a great part of the town is built on a hard rock. That is erroneous. Altona rests on the same formation of soil as the whole north-German geest and as the greater part of Hamburg too. Furthermore, at Altona away from the river there are no low-lying and poor districts where the death-rate from cholera was very much higher than in the upper parts of the town. It is true I omitted in my lecture detailed descriptions about the distribution of the cases of cholera in the geest districts and the marshland of Hamburg and Altona, also about the influence of the average wealth and of the density of population, &c. I was afraid to trespass the borders of my paper and I contented myself to state the geest was attacked as severely as the marsh. However, abundant information about all those conditions is published in my "Jahresbericht uber die Medizinische Statistik des Hamburgischen Staates, 1892," and by Gaffky in vol. x. of the "Veroffentlichungen des Kaiserlichen Gesundheitsamts." The figures you quote are taken undoubtedly from these sources. You will find there ample evidence why Gaffky and I attributed to the water-supply the prominent rôle in the spreading of the large epidemic of 1892. I cannot hope that our reasons might convince you but I trust you will see that all questions raised in your article are extensively investigated by us.

I am, Sirs, yours faithfully,

Hamburg, May 2nd, 1904. DR. REINCKE.

THE EAST LONDON MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—A society bearing this name has been formed to deal with subjects of medical interest but primarily to press for a reform of the abuse of hospital charity. An open meeting will be held on Tuesday, May 17th, at 3.30 P.M., in King's Assembly Rooms, Cottage Grove, Mile End-road, near Burdett-road, E. Circulars are being sent to as many medical practitioners as possible in East and North-East London, but as some may not receive them will they be kind enough to accept this as an invitation to attend.

We are, Sirs, yours faithfully,

GEORGE BLACK,
EDWIN HASTINGS,
F. HARRIS WHITE,
} Honorary Secretaries *pro tem.*

White House, Tredegar-road, Bow, E., April 30th, 1904.

ON CONTINUOUS CLINICAL TEMPERATURE CHARTS.

To the Editors of THE LANCET.

SIRS,—Some years ago while house physician to Dr. J. K. Fowler at the Middlesex Hospital I was studying the different types of temperature charts met with in cases of pulmonary tuberculosis. To some of these, notably the inverse type, where the early morning temperature is higher than the evening temperature, being a continuation of the evening rise, Dr. Fowler attached some importance, for its appearance sometimes heralds the onset of acute general tuberculosis. *It then occurred to me that a continuous* record of a patient's temperature registered on an automatically moving chart might show recurring variations which by our present method of charting temperatures remain unobserved, but which, if observed, might throw some light on the nature or progress of an illness. Mr. Whipple of the Cambridge Scientific Instrument Company kindly placed one of Callendar's electric recorders at my disposal, and he also took considerable trouble in preparing suitable terminals for making clinical observations. Ultimately a glass bulb after the pattern and size of one of Messrs. Burroughs, Wellcome, and Co.'s enules was made and this, carrying the fine platinum wires, was used for taking either axillary or rectal temperatures. Dr. Fowler kindly gave me permission to use the recorder in his wards. The instrument yielded excellent and accurate results though there was some difficulty in standardising it. The patients, however, objected to the constant wearing of the bulb in the axilla which caused some discomfort after 24 hours. By making the bulb flat this inconvenience might be overcome. Shortly after this I took up practice here and had, therefore, to desist from further experiments, but I have been much pleased to read in THE LANCET of Feb. 27th, which arrived by the last mail, that Professor Ronald Ross has made some further experiments, apparently with the same apparatus. I sincerely hope that these experiments will be continued.

Records of continuous temperatures offer a new field for research and the results are likely to prove of value. Thus the sudden fall of temperature which usually follows a perforation of the bowel in enteric fever or the hyperpyrexia of rheumatic fever would be instantaneously and automatically recorded, or again the fall of temperature resulting from shock might be observed during the progress of a major operation. But besides *registering the temperature of a part* of the body at any particular moment Callendar's recorder may be made to register the difference between the temperatures of any two parts—e g., the difference between the axillary and the rectal temperatures. This is done by using two separate terminals, one of which is placed in the axilla and the other in the rectum; the difference in temperature between the two bulbs is recorded in a single curve. The difference between the axillary and the rectal temperature is sometimes considerable (as in cholera) and this is a subject that may repay further study. Should the investigation prove fruitful it is to be hoped that someone may devise an instrument of smaller dimensions and less cost.

I am, Sirs, yours faithfully,
O. Reissmann, M.A., M.D. Cantab., B.Sc.,
Adelaide, South Australia. M.R.C.P. Lond.

BRITISH HOME AND HOSPITAL FOR INCURABLES.

To the Editors of The Lancet.

Sirs,—Amongst your notices of "Donations and Bequests" I see the name of the late Mr. William Sutton, M.D., but you do not mention a legacy of £250 left to this institution by him. If only out of justice to the deceased gentleman I shall be glad if you will insert this in your next issue.

I am, Sirs, yours faithfully,
April 29th, 1904. Edgar Penman.

WELSH MEDICAL DINNER.

To the Editors of The Lancet.

Sirs,—It has been decided to hold a Welsh medical dinner at Prince's Restaurant, Piccadilly, London, W., on May 25th, 1904, at 7 for 7.30 P.M. Sir John Williams, Bart., has kindly consented to preside. Gentlemen intending to be present or to introduce guests are specially requested to give notice in writing to either of the honorary secretaries as soon as possible. A general meeting will be held at 6.30 P.M., at which all should endeavour to be present, to discuss the advisability of instituting an annual reunion.

We are, Sirs, yours faithfully,
T. P Beddoes, } Honorary Secretaries.
William Lloyd, }
63, Wimpole-street, Cavendish-square, W., May 3rd, 1904.

TESTING THE EYESIGHT OF THE NATION.

To the Editors of The Lancet.

Sirs,—With reference to a recent article in the *Times* newspaper under the above heading, which is commented upon in The Lancet of April 16th, I am authorized by my council to state that the Optical Society, which is mainly a scientific society, as I show in my subsequent quotation of its objects, does not at this stage commit itself to any definite opinion on the sight-testing question nor can it accept responsibility for the views of individual members; moreover, it does not organize or conduct examinations or grant "diplomas" of any sort whatever.

In the article I quote it is mentioned that the *Optician and Photographic Trades Review* is stated to be the official organ of the Optical Society. That journal is the official medium for the publication of the society's notices and proceedings but it is in no sense authorized to voice independently the opinions of the Optical Society as a body. Moreover, I have the authority of the editor of the *Optician and Photographic Trades Review* for the assertion that neither he nor the *Official Journal* had anything to do with sending out the so-called "circular communication."

As a matter of interest to your readers I shall be glad if you will permit me to state that the objects of the Optical Society (which was founded in the year 1899) are: (1) to promote intercourse between those interested in the science of optics in the United Kingdom, the colonies, or foreign countries; (2) to foster and to disseminate knowledge of optical matters among its members; (3) to arrange lectures, discussions, and demonstrations on optical science and optical instruments; (4) to provide its members with information on all optical subjects of interest; (5) to promote the establishment, adoption, and recognition of standard sizes, gauges, calibres, templets, and methods for universal use with all optical and other scientific instruments; and (6) to print, publish, sell, lend, or distribute the proceedings or reports of the society or any papers or communications on optical science or subjects connected therewith.

I am, Sirs, yours faithfully,
W. Salt, honorary secretary.
Hanover-square, London, W., May 3rd, 1904.

THE TENURE OF OFFICE OF THE MEDICAL OFFICER OF HEALTH.

To the Editors of The Lancet.

Sirs,—It is extremely satisfactory to note that the Local Government Board has recently in some instances signified to district councils its willingness to consider favourably applications made as to the reappointment of medical officers of health without limit of time where the officers in question have been in office some years and have discharged their duties satisfactorily. The duties which have to be discharged by a conscientious medical officer of health are so important and often so diametrically opposed to the views of some individual members of a district council that where after a trial of two or three years a medical officer of health has satisfied the Local Government Board as to his discretion and competency that body should certainly see to it that the public do not lose a valuable servant through the caprice of a district council.

The reappointment without limit of time is as essential for rural district medical officers of health as for urban if sanitary reforms, which are at the present time a pressing necessity, are to be satisfactorily achieved. I have in mind more particularly at this instant the cleanliness of our milk-supplies. It is a matter of common sense that reform in this direction should begin at the fountain head—in short, with the cow. Security of tenure is essential if the medical officer of health of a rural district council is fearlessly to enforce the provisions of the Dairies, Cowsheds, and Milkshops Order and of the Model Regulations framed by the Local Government Board under Art. 13 of that order. No district council should have the power to terminate the appointment of a medical officer of health except on the ground of his incompetency and then only with the approval or endorsement of the Local Government Board.

I am, Sirs, yours faithfully,
May 2nd, 1904. Public Health.

To the Editors of The Lancet.

Sirs,—In The Lancet of April 30th, p. 1239, one of your correspondents drew attention to the fact that the Dolgelly rural district council had fallen in with the suggestion of the Local Government Board and appointed its medical officer of health "without limit of time." Probably few of your readers are in a position to appreciate the great practical importance of what appears to be a small administrative detail. No apology need therefore be offered for emphasising the advantages that would accrue were the Local Government Board invariably to take this course and were all local authorities equally amenable to advice from headquarters.

Under present conditions the majority of provincial medical officers of health are appointed for a *short term* of years, usually, indeed, for one year only. This means that at the end of that term a medical officer who has refused to prophesy smooth things or has been in any way too active may be got rid of by the simple process of refusing to vote for his reappointment. It also means that every year the jerry-builder, the slum-owner, and the crank have a golden opportunity of making themselves more than commonly offensive by publicly objecting to the reappointment. In many districts this is a chance which is never missed, as the writer knew to his cost when medical officer of a small urban district. In such circumstances it can hardly be a matter for wonderment if the nature of the average official sometimes is subdued to what it works in, like the dyer's hand, and that annual reports tend to become too complacent. To take a concrete instance, it requires no small amount of force of character for the medical officer of a rural district to insist on dairy and cowshed regulations being strictly enforced when he *knows* that nearly every member of his authority is both by interest and by prejudice opposed to such enforcement, but it needs very considerable courage when the officer's very livelihood is imperilled if he tenders unwelcome advice. Fortunately that courage is frequently in evidence, but in any case there is a temptation to let things slide, which is bad for all concerned and especially for the public whose interests the medical officer is supposed to guard.

Now, Sirs, some of your readers are members of local authorities, while many others occupy positions of influence throughout the country, and I would suggest that they could render a greater service to public health by insisting that all appointments should be made "without limit of time." This would not only have the effect of diminishing opportunities for petty tyranny but would give security of tenure to those medical officers whose salaries are partly paid from Imperial sources, as such officers cannot be removed during the term of their appointment except with the consent of the Local Government Board. Will not THE LANCET again assist us by advocating such a far-reaching reform?

I am, Sirs, yours faithfully,

May 4th, 1904. HAUD IGNARUS MALI.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

THE MANCHESTER MEDICAL GUILD AND THE BRITISH MEDICAL ASSOCIATION.

THERE is nothing of a particularly sensational character to record in regard to the Manchester Medical Guild. During the last three or four years this organisation has kept on in the even tenour of its way. It has not retrograded nor has it made any notable step forward. If it is the best-governed people that have no history the Manchester Medical Guild may claim that, according to this axiom, it must be a model institution. If, however, there is nothing startling to record there has been much quiet, steady work done. To begin with, the monthly meetings of the guild have been regularly held and these very effectively help to keep the members in touch with each other; then for those who may fail to attend all these gatherings there is the *Medical Guild Quarterly* which constitutes a periodical official record of what has been done; but, not content with their monthly meetings and their quarterly publication, there is now a further effort being made so that the members may come into still closer and more constant association. A scheme brought forward long ago, but which fell through, has now been revived and it consists of creating a medical social and scientific club. The guild has more than 200 members and this would constitute a good nucleus for a club. But there are other medical societies to whom a common meeting place would be of use and they might join hands so as to have one great central meeting place for all the societies and organisations formed by members of the medical profession. Apart from ordinary accommodation, this club should have one or more fairly large committee rooms so that the various societies, such as the Medical Guild, the Medico-Ethical Association, and the Clinical Society of Manchester, might have their meetings at the club. The rent which these societies pay for offices or meeting places could then go to the maintenance of the club and all that is of interest to the profession could be concentrated in one single building. This evidently would be the best means of insuring success and it is to be hoped that individual predilections will not stand in the way of union for so useful and so agreeable a purpose.

Of course, though in a quiet way, the guild has helped to settle and to prevent disputes, and this not only in Manchester and Salford but also in outlying districts. For instance, at some large coal-pits in the Pendlebury district there was a dispute. The employers compelled all their men to insure against accidents but some of the miners had a society of their own and as neither organisation could agree as to who should pay the medical attendant the latter ran every risk of not being paid at all. The medical profession being organised, however, and able to present a united front was strong enough to enforce the acceptance of an agreement. It was then settled that the men's society should limit its action to the payment of benefits such as sick allowances, while the fund collected by the employers should serve to pay the fees of the medical attendants. There was, however, another difficulty. The agreement is that the colliery surgeons receive 15*s*. for every case of accident. Of course, this is remunerative only on condition that the trivial accidents are included but it had become the practice to send minor cases to the dispensing druggist. This has been altered and the colliery surgeons having now to attend the slight as well as serious cases the average of 15*s*. per case becomes reasonably profitable. When the colliery surgeons first insisted on these points there was an outcry. Threats were made that advertisements would be published inviting some outside practitioner to come to take the place of the old-established colliery surgeons but when it was found that the latter were really well organised all such resistance was abandoned and the colliery surgeons won their contention all along the line.

Though there has been comparative calm for some years now it seems very probable that a storm may burst at no distant day. The trouble which arose during the course of last year with the Manchester and Salford Provident Dispensaries Association has already been described.[1] These dispensaries are providing municipal servants with medical attendance for 3*s*. 6*d* per annum. Even the workmen themselves very generally recognise that this is not enough. Some three or four years ago an interview took place between representatives of the Manchester Medical Guild and officials from the local friendly societies and sick clubs. The discussion which ensued showed that the objection was not so much against an increase in the amount of the subscription paid but the fear that one concession if made would lead to agitations for further increase. If the medical profession could only decide once and for all—and this all over the country—what would be considered as permanently satisfactory there would be some prospect of coming to an understanding. The Manchester Medical Guild proposes to act upon this suggestion. There should be a minimum charge for contract work which should be recognised in every part of the country and enforced on every society. But this is beyond the power and scope of the medical unions that have been constituted to deal expressly with economic questions. These unions, though becoming more numerous, are still confined to certain counties, towns, and localities. Here, then, is an opportunity for the British Medical Association since its branches are established all over the country. Consequently the Manchester Medical Guild proposes to arrange so that at the next
Medical Association a motion
the minimum for contract wo
be 4*s*. per annum.

The new constitution of the British Medical Association has caused confusion and doubts to arise in the ranks of the various medical unions such as the Manchester Medical Guild which had been constituted to take action in regard to economical and ethical questions. It was but natural to imagine that these unions would merge in the new divisions and branches of the British Medical Association. Theoretically this seemed the best course to follow but for the time being at least it would not work in practice. The medical unions have gained substantial advantages. There is much that remains to be done but already very palpable benefits have been attained. To abandon these means of action could only be compared to the proverbial loss of the bird in the hand for the sake of two in the bush. The Manchester Medical Guild in any case, as one of its members stated, does not feel inclined to commit suicide for the sake of a paper constitution. Then there are fundamental differences. A medical union differs in the recruiting of its members from all other medical societies or organisations. Most societies are pleased to enrol men of standing and of the best repute. A medical union is also pleased to bring together those members of the profession who hold the best position; but its main object is, on the contrary, to get at the poorest of practitioners. It is from those who are on the lowest rung of the ladder that a disastrous competition may be feared. They tend to lower the standard of living and the dignity of the profession. Consequently it is most necessary to bring them under the discipline and moral control of a strong professional union. Then with these less fortunate members of the profession the question of subscription, which in many instances is not more than 5*s*. a year to cover the working expenses of the medical union, is a matter of consideration. Thus it happens that many members of the medical unions are not, and would have some difficulty in becoming members of the British Medical Association. If, however, this end is ultimately to be attained the British Medical Association must first prove that it thoroughly grasps the questions at issue and that it has the intelligence, the power of initiative, and the enterprise to grapple with them effectively.

---

[1] THE LANCET, April 30th, 1904, p. 1236.

The proposal which the Manchester Medical Guild hopes to see brought forward at the Oxford meeting of the British Medical Association will serve as a preliminary test. It will be a splendid opportunity, for this is a matter that could be settled more effectually by the British Medical Association than by the medical unions even if they were all unanimous. It is quite natural that the friendly societies and other such bodies should say that they first of all want to know what it is the medical profession really does desire. The Manchester Medical Guild may answer that they desire a minimum of 4*s.* for contract work, but it may be shown that at Southampton and elsewhere the payment of 5*s.* and even 6*s.* has been enforced. While in some places medical men have accepted as little as 2*s.* 6*d.* per annum they have asked double and treble as much elsewhere. The friendly societies and sick benefit clubs may well complain that the medical men do not know what they want. But the gathering at Oxford will afford a unique opportunity of getting something like uniformity introduced in regard to the demands that shall be brought forward in the future.

One of the greatest objections that can be made against the medical unions as they exist to-day is their isolation. They have to deal with bodies that are not isolated. The great friendly societies are national institutions governed by central committees with branches all over the country and the colonies. This gives them a distinct advantage which the action of the British Medical Association might effectively counteract if that body could prove itself competent to deal with such questions.

In the meanwhile, though hoping to make the minimum for contract work a national question, the Manchester Medical Guild is pushing the matter forward as a local question. In 1899 a pledge was circulated asking the local practitioners to promise that they would not accept any contract work for less than 4*s.* a year. This had a good effect at the time and many clubs raised their rate of payment accordingly. But some club medical officers feared to take action, giving as their excuse that the pledge had not been unanimously accepted. Others while agreeing with the principle did not like the idea of signing a pledge. Then there was the competition of the "sixpenny doctors" who had been neglected and who would offer to do the club work whenever any difficulty arose between the clubs and their usual medical officers. Indeed, this question of the "sixpenny doctors" is an important matter which has been too readily set aside. Just as it is necessary to establish a minimum rate of subscription for contract work, so also there should be a minimum fee for consultations. In the meanwhile exception may be taken to the minimum proposed by the Manchester Medical Guild. It should be not 4*s.* per annum but 1*d.* per week—that is, 4*s.* 4*d.* per annum. As only poor people should be allowed to contract at such rates they must pay by the week and 4*s.* a year would mean that during four weeks no collection would be made. If a man can pay 1*d.* during 48 weeks the probability is that he can do so during the whole of the 52 weeks into which the year is divided. It would in any case be an excellent measure to fix on some such limit and it is to be hoped that the Manchester Medical Guild will not fail to press the matter forward.

LITERARY INTELLIGENCE.—Messrs. H. K. Lewis are just issuing the eleventh edition of Martindale's Extra Pharmacopœia, revised by Mr. W. Harrison Martindale, F.C.S., and Dr. W. Wynn Westcott. The book has been considerably remodelled, many of the older drugs, chemicals, and preparations having been omitted and 300 new remedies being included. The sections on antitoxins and organotherapy have been almost entirely rewritten. —*The Electrician* Printing and Publishing Co., Salisbury-court, London, announces that it will issue early in May an important work by Mr. F. Soddy, M A., entitled "Radio-Activity: an Elementary Treatise from the Standpoint of the Disintegration Theory." This is intended as a text-book for students and others interested in the fascinating research work connected with radium and other radio-active substances.

THE GERMAN SURGICAL CONGRESS.[1]

(FROM OUR BERLIN CORRESPONDENT.)

(*Continued from p. 1236*)

Operations on the Brain.

PROFESSOR MADELUNG (Strasburg) described the case of a boy, nine years of age, who received a gunshot wound of the brain three years ago and had since suffered from amaurosis, slight hemiparesis, and general disfigurement from excessive adiposity. From the situation of the wound and from the appearances presented by skiagrams he concluded that the hypophysis had probably been injured.

Dr. STOLPE (Breslau) said that in a man 40 years of age who had suffered from acromegaly and general adiposity he had found adenoma of the hypophysis and a metastatic deposit in the right occipital lobe.

Professor VON EISELSBERG (Vienna) said that he had made experiments on the hypophysis of cats and had found that complete removal of it always caused the death of the animal.

Dr. BORCHARD (Posen) mentioned the case of a girl, nine years of age, who, three years after a serious injury to the skull, showed symptoms of mental impairment. The skull was trephined and an abscess was opened, with the result that the psychical troubles disappeared. Dr. Borchard was of opinion that they were due to local irritation of the brain.

Dr. FRIEDRICH (Leipsic) said that he had seen a patient who, after a traumatic lesion of the brain ten years ago, suffered from mental disturbance but recovered after removal of a large growth in the frontal lobe.

Professor HILDEBRAND (Basle) reported the case of a patient who, two days after an operation on the nose, in the course of which the galvano-cautery was used, suffered from marked pyrexia, slow pulse, paresis of the nervus abducens, protrusion of the eyeball, œdema of the eyelids, and mydriasis. As there probably was thrombosis of the cavernous sinus he gave several injections of Tavel's antistreptococcic serum. Notwithstanding the development of slight erysipelas at the place of the injection all the symptoms eventually disappeared, the paresis of the nervus abducens being the longest maintained.

The Function of the Thyroid Gland.

Dr. LANZ (Amsterdam) read a paper on the procreative faculty of animals whose thyroid gland had been removed. He found that the loss of this gland produced in moderately young animals sterility which was but little influenced by feeding with thyroid gland or by the administration of iodine. As to the human genus he alluded to the case of a male cretin, aged 28 years, in whom sexual desire had been absent previously to the administration of thyroid gland but thereupon it appeared at once. He afterwards married but had no children. In a female cretin menstruation made its appearance only after thyroid feeding.

Intrathoracic Operations.

Dr. SAUERBRUCH (Leipsic) read a paper on a pneumatic apparatus devised by him for the prevention of pneumothorax in intra-thoracic operations. It consisted of a kind of chamber in which the pressure was reduced by an air pump. It was first tried in operations on animals; the animal was put into the chamber so that only its head was outside and an air-tight junction was made by means of a caoutchouc ring. The operator and his assistants were inside and the anæsthetist was outside the chamber. The principal feature of Dr. Sauerbruch's apparatus was that the respiration continued to be normal after the thorax was opened, the difference of pressure between the bronchi and the pleural cavity being kept constant.

Professor VON MIKULICZ (Breslau), in whose clinic Dr. Sauerbruch had made his experiments, confirmed the statements contained in the paper and expressed his views as to the future of intra-thoracic operations with the aid of Dr. Sauerbruch's apparatus.

Professor PETERSEN (Heidelberg) recommended instead of Dr. Sauerbruch's method the subjecting of the bronchial system to increased atmospheric pressure. For this purpose he used an apparatus similar to Waldenburg's pneumatic apparatus, by means of which compressed air was respired.

---

[1] For this report we wish to tender our thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our correspondent.—ED. L.

Abdominal Surgery.

Professor VON MIKULICZ discussed some methods of increasing the resistance of the peritoneum against infection in operations on the gastro intestinal organs. He explained that a trustworthy disinfection of the peritoneum was very difficult and that prophylactic injections of serum were useless, the efficacy of the antistreptococcic sera being hitherto rather doubtful. The best method was to produce artificial hyperleucocytosis by the administration of nucleic acid; 12 hours previously to an operation 50 cubic centimetres of a 2 per cent. solution were given. Of 34 patients suffering from serious diseases of the stomach and intestines none died from the operation, a result which Professor von Mikulicz attributed to the above proceeding. Administration of a saline solution was likewise efficacious.

Dr. BRUNNER (Munsterlingen) read a paper on the difference of virulence of the contents of the duodenum and the colon. He said that perforation of the duodenum was much more dangerous than that of the colon and that the bactericidal action of the peritoneum showed great differences in individual cases. He then gave an account of experiments made on animals for the purpose of destroying the bacteria of the intestines, especially bacterium coli; he found injections of acids to be the most efficacious method.

Dr. KADER (Breslau) expressed the opinion that peritonitis might be avoided by giving an injection of antistreptococcic serum ten hours previously to an operation. He even recommended the giving of prophylactic injections to every soldier 24 hours before a battle.

Professor KUSTER recommended in septic peritonitis the making of a small incision through which a drainage-tube or a strip of gauze might be introduced; the patient must then be kept permanently on the back even when the dressing was changed. This position was, of course, very tiresome and even insupportable to certain patients.

Professor FRIEDRICH (Greifswald) read a paper on subcutaneous feeding of patients operated on for gastro-intestinal diseases or for peritonitis where the administration of food by the mouth or rectum was unavailable. He recommended the injection of about 60 or 70 grammes of glucose and of the same quantity of olive oil; to meet the want of albuminous substances he recommended injections of a pepsin-peptone solution. In this way a patient might be sustained for some time.

Dr. PAYR (Graz) drew attention to thrombosis of the veins of the intestine, the mesentery, and the peritoneum which sometimes produced profuse hæmorrhage from the gastro-intestinal vessels and might occur in strangulated hernia and in appendicitis.

Professor RIEDEL showed specimens of perforated gastric ulcers. The prognosis of peritonitis in those cases was rather bad, and an early diagnosis of ulcer was therefore essential from a surgical point of view. The ulcer was in the majority of cases situated on the small curvature and on the pylorus; pain was as a rule felt on the left side and usually appeared so early that by careful dietetic treatment the patient might sometimes be saved

Dr. FRANKE (Altenburg) showed a patient suffering from cancer of the pylorus in whom he had first performed gastro-enterostomy and four weeks afterwards resection of the growth. He explained the advantages of this proceeding.

Dr. SEEFISCH (Berlin) said that three years ago he had performed gastro-enterostomy for stenosis of the pylorus in a child now four and a half years of age. The Murphy button was found to be present in the stomach one and a half years after the operation; by a recent radiogram it was, however, ascertained that the button had in the meantime been spontaneously discharged.

Dr. BORCHARDT (Berlin) mentioned the case of a patient suffering from aneurysm of the aorta who showed uncertain symptoms of dilatation of the stomach after a grave injury of the abdomen. The patient died on the fifth day and the necropsy revealed volvulus of the stomach and complete obstruction of the pylorus and the cardia.

Dr. LAMPE (Bromberg) discussed the functional troubles of the gastro-intestinal canal following gastro enterostomy according to the method of Wolfler and Lucke. They were, he said, caused by œdema and might be avoided by introducing an absorbable drain into the anastomosis.

Dr. VON BECK (Carlsruhe) said that he had investigated 500 cases of colitis, of which 170 occurred in men and 330 in women. They were a sequel to different abdominal diseases—perityphlitis, enteroptosis, cancer, tuberculosis, and actinomycosis of the colon. In six of his own cases he cut out the entire colon from the circuit by joining the ileum to the sigmoid flexure—i.e., performing an ileo-sigmoidostomy. One of his patients died but the others recovered.

Dr. BUNGE (Berlin) spoke on the causation of subcutaneous ruptures of the intestines, which arose either from direct crushing or from bursting or from distension. The rupture happened in the majority of cases between the ileum and the cæcum or between the sigmoid flexure and the rectum. Rupture of the mesentery was particularly dangerous.

Professor WULLSTEIN (Halle) said that he had made numerous experiments on resection of the intestines and the stomach without opening the lumen. The principal feature of his method was that the serosa was sutured first over an absorbable button, the walls of the intestines being then compressed by a special instrument. This method of splanchnotripsy was used in invagination, in appendectomy, and in gastro-enterostomy.

Dr. RIESE (Britz) mentioned two cases in which after an operation gauze compresses had been accidentally left in the peritoneal cavity. In one case the compress was in the intestine, in the other it was in a mesenteric cyst. Both cases were successfully treated by laparotomy. No inflammation ensued, the gauze being aseptic.

(To be continued.)

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Medical Arrangements with the Tibet Mission.—The Plague Epidemic.

THE medical arrangements with the Tibet Mission not only provide for our own sick and casualties but also as a civilised power for medical aid to the Tibetans. It must be borne in mind that there are hosts of followers engaged in road making and transport to be provided for and that from the base at Siliguri at the foot of the Himalayas the road goes through the tropical Teesta Valley and then upward for 150 miles or more through the most difficult and inhospitable mountains in the world. Up to the present the daily sick list has averaged 100 fighting men and about 200 followers. The medical establishment is under Lieutenant-Colonel L. A. Waddell, C.I.E., I.M.S., and consists of 16 executive officers, 31 assistant surgeons and hospital assistants, a large staff of nursing orderlies, and assistants with ambulance, transport, tentage, stores, comforts and other impedimenta in abundance. At each chief stage of the journey there has been established a section of a hospital and at small intervening posts a hospital assistant with medicines. Hospital huts are now being built to replace the tents. The ambulance transport is a host in itself. Besides eight stretchers per regiment there are about 50 doolies each carried by six bearers and also ambulance chairs, riding ponies, and for the road up the Teesta Valley a dozen bullock tongas. As the Indian doolie-bearer is no good for the mountains and the cold, some 300 Tibetans and Sikhimese were engaged as bearers but many of these deserted. At the action at Guru, after our own wounded had been attended to, the medical officers rendered help to the enemy's wounded and about 180 were carried from the battlefield to Tuna and Guru villages.

The plague returns for the week ending April 2nd show 46,320 deaths compared with 39,975 in the preceding week. The provinces were affected as follows: Punjab, 19,322 deaths, against 12,594; United Provinces, 8610, against 8776;
[illegible] against
Bom [illegible] India,
4109 [illegible] out the
1469 [illegible] cline to
loca [illegible] st 471.
814 [illegible] ashmir
but [illegible] in the
repo [illegible] ng the
Punjab [illegible]
week, the remaining provinces nearly all showing a decline. After being free from the disease for so many years plague has broken out in Madras city. Ten indigenous cases are reported partly in the city itself and partly in an adjoining village.

April 15th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Food Adulteration in the City.

THE report of the borough analyst shows that this form of dishonesty is on the decrease in Birmingham. The total number of analyses last year was 1660, of which 1303 were conducted under the provisions of the Sale of Food and Drugs Acts and the remaining 357 under applications from the various Government departments. The samples submitted under the Acts represent only 2·4 per 1000 inhabitants, this being a smaller proportion than in the preceding year. It is also a much smaller proportion than that in London where the number of analyses amounts to 4 per 1000. 532 samples of milk were dealt with during the year with the result that 450 of these samples proved to be genuine. Of 368 samples of butter examined adulteration was found to have taken place in 21. The worst sample of milk examined was taken from a milk-cart and contained 29 per cent. of added water, 20 per cent. of skim milk, and a small quantity of boric preservative.

The Arley Small-pox Outbreak.

This outbreak, which originated at Arley near Nuneaton, has not only affected the union at that place but also those of Atherstone, Foleshill, and Meriden. About 30 cases have been notified and the majority of these are under treatment at the isolation hospital at Binley. The medical officer of the Nuneaton rural district council, which authority will have to bear the bulk of the cost of dealing with the epidemic, has prepared a special report which shows that in one house in Arley there were six children, of whom four were vaccinated and two unvaccinated; the two latter contracted small-pox whilst the four others escaped. In another house there were six children, three vaccinated and three not. The three who were vaccinated escaped small-pox and the three who were unvaccinated contracted it. In another instance there were in one house six unvaccinated and three vaccinated persons and only the latter escaped the disease. The medical officer thinks that there may be a few further odd cases but he does not expect any serious development of the epidemic. Mr. W. H. Boon, the chairman of the rural district council, has intimated that when the epidemic is over he will call attention to the greatly increased cost to the ratepayer incurred through persons refusing to be vaccinated and subsequently falling a prey to small-pox.

The New Women's Hospital.

The foundation-stone of the new hospital was laid a few days ago by Mr. Arthur Chamberlain, the president of the institution. The present building, which is situated in Stratford-road, Sparkhill, has long been too small for the needs of the city and district and the new building which is being erected at Showell Green-lane, Sparkhill, will be of much larger size. The hospital grounds abut upon the Sparkhill Recreation Ground, which is 17 acres in extent, so that there will always be a certainty of abundant fresh air. Prior to the stone-laying ceremony the annual meeting of the supporters of the institution was held and the report of the committee was read. During the year 1903 3450 cases had been treated at the out-patient department, this being an increase of 161 on the previous year. The total number of new and old cases treated had been 19,370, being 1292 more than in 1902; 444 patients had been admitted to the in-patient department, an increase of 18; the number of operations had been 426, an increase of 14; and the number of cases involving abdominal section had been 250, 16 more than in the previous year. Of these 10 had died, giving a death-rate of 4 per cent. as compared with 1·28 per cent. on 234 operations in 1902. From the founding of the hospital in 1871 up to Dec. 31st, 1902, there had been 3610 operations; of these 218 patients had died, giving a death-rate of 6 03 per cent. The amount which the new hospital is to cost is £40,000, towards which the treasurer has up to the present received £32,000. The new hospital will be in the main a two-storey building of brick. The elevation will be of an unobtrusive character and will not be adorned with any terra-cotta and with but little stone. In the centre is the administrative block with entrance hall, matron's and medical officers' rooms, nurses' and servants' dining rooms, &c. On the first floor, which is approached by two wide fire-resisting staircases, are the sleeping rooms and bath rooms for the matron, medical officers, and servants. At the back of the administrative block are placed four ward units, two on each floor, having a total provision for 48 beds. These are approached from the administrative block by a central corridor on the ground floor. Leading out of this corridor are a dispensary, surgical store, storeroom for patients' clothes whilst they are inmates of the hospital, sewing room, mattress store, and a sitting room for the sister in charge of the floor. There is also a staircase, with low steps, which incloses a lift-shaft in which is an electric lift capable of containing a patient in bed and with a nurse in attendance. On the first floor immediately opposite the lift is the operating department, consisting of an anæsthetic room, two operating rooms, and sterilising rooms, with a sitting room for the sister in charge. Each ward unit is to consist of an associated ward for ten beds, with an isolation ward for two beds, duty room, pantry, a room for washing mackintoshes, and two sanitary annexes placed cornerwise, with balcony between, from which there is a fire-escape to the ground. There is also a bathroom placed near the main staircase, in which patients will be received before they are taken into the wards. The ward buildings are to be constructed on piers and arches allowing of a free air space below the ground floor under the whole area of the buildings as a protection against damp and ground air. A narrow balcony will run along each side of the wards on the first floor, giving patients a chance of sitting in the sun and also affording a means of cleaning the windows from without. The wall and ceiling surfaces throughout these buildings will be painted with a special enamel paint upon plaster and care is being taken as far as possible to avoid any corners in which dirt might be harboured. At the south end of the administrative block is placed a detached nurses' home containing on three floors 20 nurses' bedrooms, three sisters' bedrooms, sick-room, and on the ground floor a recreation room, small kitchen and pantry, bathrooms, &c., and a staircase at the end of the corridor. At the north end of the administrative block is a detached building for the laundry and engineering departments containing on the basement floor boiler and engine room fitted up with complete plant for an electric lighting installation, together with room for accumulators and steam disinfecting room. On the ground floor there are a washhouse and a laundry with up-to-date machinery, also a delivery and receiving rooms. In addition there is a mortuary consisting of post-mortem rooms and friends' waiting room. The administrative ward and laundry buildings are connected below ground by a subway in which will be carried the steam, water, and gas mains and electric cables. The heating will be on what is known as the "atmospheric" system. The convalescent home will be a two storey building containing on the ground floor an entrance and corridor leading to the day room, dining room, matron's sitting room, kitchen with larder, pantry, and scullery, and also a room for patients' clothes, bathroom, &c. On the first floor there will be two dormitories for patients, each containing five beds, and two for two beds, the matron's bedroom, linen room, and sanitary annexe. There will be an external fire-escape staircase from the first floor to the ground floor. It is expected that the convalescent home will be ready for occupation by September and the main buildings in the early part of next year.

Worcester and Warwick Volunteer Bearer Company.

The annual supper and distribution of prizes to this company has recently taken place, Colonel W. P. Whitcombe, the commander of the company, presiding. Colonel A. W. Duke, R.A.M.C., principal medical officer of the north-western district, was also present, as was Captain Roscoe Badger, Colonel Whitcombe's subordinate officer. Colonel Duke, in responding to the toast of his health, pointed out that his district extended from Carlisle in the north to Hereford in the south. In that district there were many volunteer brigades and many bearer companies. The company he was addressing was now only a little over one and a half years old and he had seen nothing like the results which they had achieved in any other bearer company in the midland district. There was no work in England that he looked upon as more important than the work which they were doing. Supposing this country were invaded they all knew what a great number of men might be wounded in a very few minutes. It would be impossible for the Royal Army Medical Corps of themselves to deal with them; therefore they were trying to form companies of men like them who were willing to learn how to help the wounded and the sick when they fell. The great difficulty which they found in forming such companies was the want of assistance from the civilian part of the population. Some brigades were badly in want of such help. In Birmingham they seemed to have received considerable encouragement and he should like to see the people in other places encouraging the men who formed such companies by attending at their gatherings and offering prizes for their competitions. He thought that the greatest credit was due to Colonel Whitcombe and Captain Badger for what they had done.

May 2nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"Tramp Factories."

AT a conference of women guardians held on April 28th in the Manchester town-hall, under the presidency of the Lord Mayor, Mrs. Higgs of Oldham made some strong remarks on the need of re-moulding the present system of dealing with the homeless. By the Poor-law of Queen Elizabeth's time it was proposed that every worker should be anchored to a parish and nobody should be idle. But to-day the decline of agriculture and the growth of "industrialism made it necessary that labour should flow readily from one manufacturing district to another," and such migration should be facilitated. In tramp wards the "tramp" proper and the genuine seeker for work should be distinguished and the latter, man or woman, should be allowed to stay in a town long enough to look for work. Mrs. Higgs spoke from personal experience of tramp wards and common lodging-houses. She said that women who entered a tramp ward scrubbed floors "and for their night's lodging did a day's work worth at any rate 2*s.* and good food. Yet they emerged from the ward half starved and worn out after a long, weary, foodless day." As it is undoubted that the chronic tramp is one of the chief agents in spreading small-pox and other diseases it is desirable that he should be dealt with differently from the genuine seeker for work, however difficult the separation of the two classes may be. The tramp question came up at a meeting of the Cheshire Standing Joint Police Committee held at Chester Castle on April 30th. The Northwich Union wrote calling attention to the tramp nuisance and suggested that a warning issued some years since by the Chief Constable (Colonel Hamersley) "not to relieve tramps or render them any assistance" should be widely distributed. The Chief Constable suggested that when tramps were brought before [illegible] them. It was decided to [illegible] doubt that besides being a [illegible] tramp is a serious danger [illegible].

Sir Henry Roscoe's Graduation Jubilee.

Although Sir Henry Roscoe cannot be claimed as a member of the medical profession it may perhaps be permissible to notice the very general congratulations on the occasion of the fiftieth anniversary of his graduation at Heidelberg as a doctor of philosophy. There was a large gathering in the Whitworth Hall of the Owens College on the evening of April 22nd of the old students of the Owens College, of university professors from all over the kingdom, and of representatives of scientific and philosophical societies, and addresses were read from these and from colonial and foreign universities. It is 47 years since Sir Henry Roscoe became connected with the Owens College when it was located in a dwelling-house in Quay-street. For 30 years he taught at the Owens College, for the last 17 years he has had the title of emeritus professor of Victoria University, while for eight years he has been Vice-Chancellor of the University of London. During his long residence in Manchester Sir H. Roscoe has always shown much interest in questions affecting the public health and medical men everywhere will join in congratulating him upon his graduation jubilee.

The Water-supply.

The annual report of the Manchester Waterworks Committee contains some interesting facts. The reservoirs, watercourses, and subsidiary works at Longdendale, representing the old supply before Thirlmere was tapped, have been maintained in good order and condition. The work of the committee has included the laying of 19 miles of iron piping and connexions made to 4991 additional houses. The full supply of water has been maintained throughout the year. The new 36 inch main from the reservoirs at Prestwich for distribution in the city of the second instalment of the Thirlmere water is nearly completed. The level of the lake itself is being raised 15 feet above the present height and this will considerably increase the storage capacity. This increase is necessary in view of the demand that will be made when the second line of pipes from Thirlmere is completed, as it soon will be. The hydraulic power supply has been well maintained and is extending. The average weekly output of water for the year is 3,590,900 gallons, as against last year's average of 3,565,900 gallons, an increase of 25,000 gallons per week. How long the present supply will suffice is of course as yet unknown, but if the population continues to increase it will be a matter for careful calculation. It will be difficult to find another Thirlmere unappropriated.

"Clean Heads."

We English think ourselves a clean people but we might be cleaner. In some sections of the population the tolerance exhibited towards parasitic pests is something marvellous. In a discussion at a meeting of the Clitheroe education committee Mr. W. E Musson, an old practitioner there, said he had examined as many as 60 children and found that not more than six or seven had absolutely clean heads. He spoke of the hardship it was to have to send children among those of negligent parents, for no amount of care would keep children's heads clean if they were among others who were unclean. A motion was adopted that where slates were used in schools the practice of spitting should be rigorously suppressed and that the education committee should encourage the use of paper instead of slates as far as practicable. Presumably if the committee suppresses spitting it will supply water, with rags or sponges, for cleaning the slates and paper if used will be burned when done with. It was also decided to recommend the town council to allow its medical officer to visit each school once in three months to examine the eyes, hair, and teeth of the children and that his present salary should be increased by £15 a year. It is to be hoped that the town council will agree to this modest request and some such arrangements should be general, though three-monthly examinations give too much time for parasites to run riot.

Death from Anthrax.

An inquest was held on April 28th on the body of a butcher living near Nantwich who was suspected to have died from anthrax. The evidence showed that on March 31st he dressed the carcass of a cow that was afterwards sent to Manchester market. He became ill and died on April 25th. The owner of the cow said that it died after a few hours' illness and the veterinary surgeon told him from "milk fever," that he said the cow was a good bit of beef, and advised him to make the best of it. The evidence showed that the cow was dead before the veterinary surgeon saw it and that at his suggestion it was dragged out of the shippon and bled. Mr. Frank E. Mathews said that death was due to anthrax. From this case and from others it is evident that there is a great deal of ignorance or carelessness or both with regard to this most dangerous disease, and that the veterinary profession, whose responsibilities in the matter are extremely serious, are not always alive to them. In this case the coroner is reported to have said "it was perfectly scandalous that cows which died from disease were stuck for the purpose of being sent to market and sold for human food." Although there may be some consolation in knowing that when well cooked no ill consequences may befall those who eat it, however nasty the idea may be, still the risk incurred by those who handle the raw meat must be considerable. The verdict was that "Death was due to accidental inoculation from anthrax bacilli," and the jury "expressed dissatisfaction with the veterinary surgeon's evidence and with the way in which he had handled the case." The matter is serious for Cheshire and every care ought to be taken that no more disastrous blunders are made. Cremation of the carcass seems to be the only satisfactory mode of dealing with these cases.

May 3rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Vaynor and Penderyn Health Report.

Vaynor and Penderyn form a rural district with a population of 4957 persons situated in Breconshire but adjoining Merthyr Tydvil and this proximity no doubt accounts to some extent for the high death rate of 19 3 per 1000 recorded for 1903. The birth-rate during the same period was 31 per 1000 and the infantile mortality-rate was equal to 189 per 1000 births. This large number of deaths among young children quite justifies the statement contained in the annual report of the medical officer of health, Mr. T. J. Webster, that the milk-supply of the district requires to be supervised carefully for now that infants are so much bottle-fed it is more than ever essential that the milk should be pure, unadulterated, and plentiful.

Llandaff and Dinas Powis Health Report.

The rural district of Llandaff and Dinas Powis is contiguous to Cardiff and is probably affected by the good sanitary conditions which prevail in that town. The population of the district is 24,205 and Dr. Richard Prichard in his annual report for 1903 gives the birth-rate as 29 per 1000, the death-rate as 12 per 1000, and the infantile mortality-rate as equal to 98 per 1000 births. It is one of the few districts in which whooping-cough has been included in the schedule of notifiable diseases for any lengthened period and although Dr. Prichard does not express any very definite opinion as to the value of the practice he gives some very instructive statistics relating to the disease. During the past 14 years 1496 cases have been notified and 86 deaths have occurred. In the first seven years there were 746 cases and 50 deaths, giving a case-mortality of 6 7 per cent., and in the second seven years there were 750 cases with 36 deaths, or a case mortality of 4·8 per cent. There would appear, therefore, to have been some beneficial influences at work and they probably include the visits of the sanitary inspector with the printed instructions of the medical officer of health to the infected houses. The high rate of mortality from the disease among very young children is well shown in the figures for 1903. Of the 37 children under one year old who were attacked eight died, while of the 168 who were over one year only one died. The scheme of voluntary notification of cases of phthisis which was adopted in the district two years ago has been discontinued.

Carmarthen Asylum.

At the end of the first quarter of this year there were 680 patients in the three counties asylum at Carmarthen and the weekly charge for maintenance for pauper patients is now 9*s*. 0½*d*. The superintendent of the institution (Dr E. Goodall) is pressing forward the question of superannuation for the officials and the asylum committee has passed a resolution approving the principle.

Talgarth Asylum.

At the Breconshire and Radnorshire joint asylum at Talgarth, which was opened last year, the weekly rate of maintenance for pauper patients is 12*s*. On March 25th last there were 245 patients in the institution.

Swansea General Hospital.

The corporation of Swansea has subscribed £100 to the funds of the Swansea General Hospital. The subscription from this source in former years has been 50 guineas.

Memorial to the late Mr. W. M. Barclay, F.R.C.S. Eng.

In the chapel of the Bristol General Hospital a brass tablet has recently been erected in memory of the late Mr. W. M. Barclay who was for many years connected with the institution. The inscription was the last composition of the late Canon Ainger, Master of the Temple, London, and is as follows:—

of Wilfred Martin Barclay, F R.C S., born

[illegible]

and personal charm which endeared him to his colleagues and to all with whom he was associated in the work of this institution.

Bristol Royal Infirmary.

The committee of the Bristol Royal Infirmary has expressed much regret at receiving the resignation by Sir Charles Cave, Bart., of the presidency of that institution. Sir Charles Cave has occupied the position for 25 years, a longer term than any of his predecessors, and has performed much useful work for the infirmary.

May 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. G. W. Beattie.

THE death occurred at Peel House, Failsworth, on April 25th of Dr. George Watson Beattie, medical officer of health of Failsworth, near Manchester, medical officer of the Prestwich union, and public vaccinator for Failsworth. He graduated M.B, C.M. at the University of Aberdeen in 1870 and proceeded to the M.D. degree in 1872. He was a member of the British Medical Association. Prior to settling in Failsworth Dr. Beattie was in practice in Ballater.

The University of Aberdeen: Commencement of the Summer Session.

The summer session at the University of Aberdeen commenced on April 26th. The attendance of students was apparently quite equal to that of former years, although the details of the numbers at the various classes have not yet been compiled. In connexion with the medical session, intimation is made of a course of instruction in anæsthetics to be conducted by Dr. A. Henderson at the Royal Hospital for Sick Children. In connexion with the lighter side of university life it is announced that the recreation park at King's College is now in first class condition for cricket and that practice at the nets may be had at any convenient time. The attention of newly matriculated students particularly is drawn to the cricket club, as it gives them an excellent opportunity of playing on the best cricket pitch north of the Tweed. The Wanderers' Club season started on April 30th with a match against the Aberdeen Royal Asylum team. It is also announced that the lawn tennis club courts are now ready for play.

Aberdeen Royal Infirmary.

It is announced that the property known as Sim's square, situated opposite the Aberdeen Royal Infirmary, has been purchased by the directors for a sum between £6000 and £7000, with a view to probable extension of the institution at some future date. There is no doubt that the policy of looking ahead in the case of a public institution like this is highly important, for it seems inevitable, considering the way in which the infirmary has grown within recent years, that development and extension will have to be made in the future and it is well that the buildings should be as much together as possible.

May 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Dispensaries.

THE report of the Local Government Board for Ireland recently presented to Parliament dealt not only with the position of the dispensary medical officers, as reported in THE LANCET of April 30th, but included a very important proposal for the reorganisation of the service. As a preamble it is stated that for the reasons already mentioned a reduction of the staff of medical officers is not only feasible but is called for in the circumstances, and, moreover, that such a diminution in the number of officers would enable a board of guardians without adding to the charge on the union funds to deal liberally as regards extra remuneration with those members of its medical staff to whom increased duties would be assigned. The report of the Local Government Board then states that "on the occurrence of vacancies in future in the dispensary medical staff they propose to consider in each instance whether the then vacant post could be abolished, and if so whether the other dispensary medical officers in the union could be placed in the charge of the extended areas and in the possession of increased salaries and their positions thereby substantially improved without inflicting any real hardship on the sick poor or imposing further burdens on the ratepayers."

National Association for the Prevention of Consumption and other Forms of Tuberculosis: Dublin Branch.

At a meeting of the committee of the Dublin branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis held at the Royal College of Physicians on April 22nd the methods of administering the oath in courts of law were considered. The committee looks upon the custom of kissing the Testament as dangerous to health and has addressed letters to the Recorder of Dublin and to the city divisional magistrates asking them to discountenance the practice in their respective courts and expressing the hope that the method of taking the oath with the uplifted hand will in future be followed more frequently.

Royal Victoria Hospital, Belfast.

The report of the working men's committee for the year ending Dec. 31st, 1903, has been published. The total amount of the working-class subscriptions for the year amounts to £3627 2*s.* 5*d.*, the largest sum ever received from the working men of Belfast and perhaps one of the largest working-class contributions in aid of any other similar institution in the United Kingdom. It is to be hoped that the employés in the shipyards will all subscribe a penny per week so that instead of £666 given by 20,000 of them more than £4300 may be contributed next year.

Seagulls and Herrings.

At a meeting of the Belfast Natural History and Philosophical Society held on April 26th Mr. John Brown, F.R.S., read a paper on the National Expenditure on the Maintenance of Gulls. He referred to the destruction of herrings by these birds and taking for his basis the hypothesis that each gull ate 200 fry in one day it would, in the two months of which its playtime lasted dispose of 12,000 fry. On the assumption that, if let alone, these baby herrings would all have matured and that the average price of herrings on the pier is about £1 per 1000 the keep of each gull for two months cost the nation £12. In the "play" of the gulls there would be about 100 birds engaged and supposing there were five "plays" per mile of coast, taking the coasts of the three kingdoms and adjacent islands, but omitting the smaller inlets, at 4000 miles they had a total of 2,000,000 birds whose keep for two months on herrings would cost 24 millions sterling. Some of the speakers in criticising the paper thought that the damage done by the gulls had been over-estimated. Probably if the herrings were left alone the sea would be overrun by them.

Public Health of Belfast.

In the report presented to the Belfast corporation on May 2nd it is stated that in the four weeks ended April 16th there were 70 deaths from zymotic disease and 111 and 204 respectively from phthisis and diseases of the respiratory organs, making a total of 315 from the two latter causes. The number of cases of infectious disease notified during the four weeks was 132, being an increase due to cases of erysipelas and "simple continued fever." Four cases of small-pox were notified, the last 16 days ago. There were 47 deaths from whooping-cough. It is owing to diseases of the respiratory organs that the death-rate (25 per 1000) is rather higher. It is hoped that the two bodies—the Poor-law guardians and the city corporation—will take joint action in reference to a consumption sanatorium.

May 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Cause and Prophylaxis of Miners' Anæmia.

ON April 19th M. Fabre read an interesting paper before the Academy of Medicine on Miners' Anæmia. From various researches which he carried out in the coal districts of France and Belgium he had come to the conclusion that miners' anæmia is only a symptom of disease and not a disease in itself (*entité morbide*). It has occurred in different mines at different periods and as epidemics of anæmia. Towards the end of the eighteenth century there was an epidemic of miners' anæmia in the district of Chemnitz in Hungary, in an argentiferous [illegible] was due to lead poisoning. [illegible] teenth century an epidemic oc[illegible] of Fresne and Vieux-Condé. Here it was apparently due to "gassing" by sulphuretted hydrogen and to other causes. The epidemic ceased on the shutting up of certain galleries in which the men affected worked and on a change being made in the methods of working. A few years later an epidemic broke out at the mine of Vanneaux near Wasmes in Belgium due to "gassing" by sulphuretted hydrogen, carburetted hydrogen, and other deleterious gases. At Ville-bœuf near Saint-Etienne an epidemic occurred in 1859 due to asphyxia by bad air. The epidemic came to an end when improved methods of ventilation were employed. There is, then, no form of anæmia peculiar to miners, but they, like everyone else, are exposed to different and ordinary causes of anæmia. These causes M. Fabre has tried to classify under the following headings: anæmias due to general influences, those due to occupational influences, and those due to individual influences either congenital or acquired. Prophylaxis consists in the establishment of good ventilation, in strict attention to cleanliness, both of the workings and of the men who work in them, and the supply of good food. All excesses must be avoided and the hours of work must not be too long. M. Blanchard said that the question of the ankylostoma in France was one of great gravity. They all knew the ravages which it had caused in Belgium and in other countries and the danger for France was also serious. M. Blanchard considered that the Academy should institute a commission of inquiry into the subject. M. Roux considered that it would be very interesting to open a general inquiry throughout the mining districts so as to discover what is the frequency of ankylostomiasis in France. An inquiry dealing with the northern districts, under the presidency of M. Calmette, had already been opened and it would appear that ankylostomiasis is very widespread in the mining districts. M. Fabre, however, said that he had examined 300 miners for ankylostomiasis and had only found one case. M. Chauveau stated that in the district of Saint-Etienne miners' anæmia was very prevalent. Perroncito has just completed an inquiry into the question so far as it affects the Saint-Etienne basin and has found numerous cases of ankylostomiasis. M. Chantemesse said that in Liège the disease was very common, so much so that the socialist societies, such as, for instance, the Ligue Populaire, had started campaigns against ankylostomiasis. When any miner offers himself for work at a mine he is not allowed to go below until he has been certified as free from ankylostoma by the medical officers of the league. The Academy eventually decided to appoint a commission of inquiry.

Local Cocaine Anæsthesia in Abdominal Operations.

M. Chaput recently read a paper before the Academy of Medicine in which he laid great stress upon the advantages of the above-mentioned method of producing anæsthesia. It does not entail the chance of death during the operation, it does away with shock and with post-operative vomiting, and the patient can take food immediately after the operation. In patients who are not very fearful the surgeon can carry out most abdominal operations under local anæsthesia. The method is always indicated when general anæsthesia would be risky; it is the method of election for all superficial laparotomies and has very real though less obvious advantages for deep laparotomies. If the patient be very nervous chloroform may be given for the continuing of the operation and the previous administration of cocaine in no way interferes with the chloroform. Under cocaine M. Chaput has performed 25 major abdominal operations, such as those for appendicitis, hysterectomy, ovariotomy, and gastro enterostomy. Most of the patients could not have taken chloroform.

Choline and Affections of the Nervous System.

At the meeting of the Neurological Society which was held on April 14th Dr. S. A. K. Wilson of Edinburgh communicated some results of a research upon choline which he has been carrying out in the wards under the care of M. Pierre Marie. Dr. Wilson stated that the presence of choline in the cerebro spinal fluid was always an indication of a nerve degeneration more or less acute. For instance, he demonstrated its presence in a case of cerebral hæmorrhage, in ten out of 12 cases of tabes dorsalis, and in epilepsy, both in the form known as "tardive" and in Jacksonian epilepsy. Choline was not found in cases of [illegible] secondary syphilis or where there was no [illegible] nerve degeneration. Dr. Wilson pointed [illegible]ss of this clinical symptom, the technique for demonstrating which is by no means complicated. He had been unable to trace any definite relations between

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.—The following candidates have passed the third professional examination as undernoted :—

Passed all Subjects.—A. Honours: P. V. Dolan. *B. Pass:* J. Bradley, M. J. Coyne, V. J. Cullen, Miss J. C. Hargraves, F. P. J. Leyrand, Leonard Lucas, J. J. McNelis, P. J. Rooney, W. Walsh.

Completed the Examination.—Israel Allsun, T. A. Bennett, W. W. Boyce, T. W. Browne, F. J. Cairnes, C. Cooper, F. A. Flynn, T. J. Galligan, J. M. Hayes, F. W. Matthews, R. A. Murphy, W. T. Morton, E. C. Mulligan, D. de C. O'Grady, A. L. O'Keeffe, M. O'Keeffe, W. J. O'Sullivan, H. E. Redmond.

Institute of Chemistry of Great Britain and Ireland.—At the Final Examination for the Associateship (A.I.C.) held in April the following candidates were successful :—

James John Ellis, B.Sc. Lond., Arthur Gordon Francis, B.Sc. Lond., James Henry Pizey, Louis John Eczekiel Riley, Reginald Tyler, Reginald William Lane Clarke, Oliver Charles Minty Davis, B.Sc. Lond., Bernard Farmborough Howard, Harold Frederick Barke, Cyril Dickinson, B.Sc. Vict., Ernest Garratt, B.Sc. Vict., Charles Edgar Male, and John Robert Stubbs, M.Sc. Vict.

Portishead Urban District Council.—At the meeting of the Portishead (Somerset) urban district council held on April 29th Dr. Charles Arthur Wigan was unanimously re-elected chairman.

Water-supply of Ilfracombe.—The new waterworks of Ilfracombe have taken two years to construct at a cost of over £50,000 and it is expected that they will be completed by the end of May. The water will be brought from the heights of Exmoor, 13 miles distant.

Death of a Notable Russian Alienist.—The *Sviet* reports the death of Dr. I. V. Constantinovski, one of the oldest Russian alienists. He had been chief physician of the Preobrezhenski Infirmary. His best known scientific work was "Russian Law on Insanity: Its History and Relation to Foreign Laws."

Munich Gynæcological Society.—Dr. H. MacNaughton-Jones, formerly university professor of obstetrics and gynæcology in the Queen's University at Queen's College, Cork, and ex-president of the British Gynæcological Society, has been elected a Corresponding Fellow of the Munich Gynæcological Society.

Donations and Bequests.—Under the will of Mr. Jean Nicolas Eugene Pierson of Heaton Chapel, Lancashire, the Manchester and Bowdon Hospital for Consumption and Diseases of the Throat and Chest will receive £400.—By the will of Mr. Joseph Pover a legacy of £200 is bequeathed to Chester Infirmary, payable on the death of the testator's widow.

University of Oxford.—The examinations for the degree of Bachelor of Medicine will commence in the Examination Schools on Thursday, June 16th. The time-table of the examinations has been published in the *University Gazette* of April 26th. The names of candidates, accompanied by the proper certificates and statutable fees, must be sent in to the secretary to the Boards of Faculties, Clarendon-building, not later than 10.30 A.M. on Wednesday, June 1st. Forms of entry, with certificate forms, can be had on application to the secretary. The examination for the degree of Master in Surgery will commence at 10 A.M. on Thursday, June 23rd.—Names must be sent in not later than 10.30 A.M. on Saturday, June 4th.

Royal College of Surgeons in Ireland.—At a meeting of the President, Vice-President, and Council held on May 3rd the following examiners were elected :—Anatomy: Ambrose Birmingham and Alexander Fraser. Surgery: F. Conway Dwyer, Andrew Fullerton, Thomas E. Gordon, and R. Lane Joynt. Physiology and histology: E. L'E. Ledwich and Charles Coppinger. Biology: John J. Burgess. Ophthalmology: Arthur H. Benson and Patrick W. Maxwell. Pathology and bacteriology: Arthur Hamilton White. Pathology: Robert Allen. Midwifery and gynæcology: Frederick W. Kidd. Sanitary law and vital statistics: Caleb J. Powell. Engineering and architecture: J. Charles Wilmot. Dental surgery and pathology: Daniel L. Rogers and William G. Story. Mechanical dentistry: George M. P. Murray and William Booth Pearsal[illegible] Lapper and Robert J. [illegible] Woodroffe. Mathematics, physics, dictation, and English essay: J. W. Tristram.

Royal College of Surgeons of England.—Mr. John Tweedy, the President, and the Council of the Royal College of Surgeons of England entertained at dinner on April 28th a number of distinguished guests, notably the Portuguese Minister, the Earl of Onslow, the Bishop of St. Albans, the Bishop of Stepney, Sir Herbert Maxwell, Mr. Justice Grantham, Sir William S. Church, Sir Lambert H. Ormsby, Sir William H. Broadbent, Sir James Reid, Sir Thomas Smith, Sir Patrick Manson, Sir Harry Johnston, Sir John Kirk, Sir Halliday Macartney, Sir William H. White, Major-General Sir Frederick Maurice, Mr. C. F. Gill, Mr. Almeric Fitzroy, Mr. Briton Riviere, Mr. H. G. Wells, and Dr. Roswell Park of Buffalo. The following members of the Council were present in addition to the President—viz., Mr. Henry Morris and Sir Alfred Cooper, Vice-Presidents, Mr. Thomas Bryant, Mr. J. Langton, Mr. A. W. Mayo Robson, Mr. H. T. Butlin, Mr. Edmund Owen, Mr. R. J. Godlee, and Mr. W. Watson Cheyne, and the secretary, Mr. S. Forrest Cowell.

Royal National Pension Fund for Nurses.—The annual meeting of this society, of which Her Majesty the Queen is the president, has just been held. Mr. Thomas Bryant presided in the absence of the chairman and moved the adoption of the report for 1903. In the pension branch the number of policies issued during the year was 953, which is the largest total for any year since the fund was established in 1887. In the last quarter of the year annuities were being paid at the rate of over £10,000 per annum under 708 policies. The actuary's report showed that the profit bonus for the quinquennium ended Dec. 31st, 1902, amounted to £27,944, or two and a half times greater than in the previous quinquennial period and this surplus was divided amongst policy-holders. The amount distributed in sick pay was £1764. The expenses of management were 3·77 per cent of the premium income. The total funds at the end of the year amounted to £820,792, an increase during the year of £86,610. The actuary's investigations again give prominence to the fact, previously established at former valuations, that nurses as a body are longer lived than women in other walks of life. The actuary, it may be mentioned, is Mr. George King, F.I.A., F.F.A., vice-president of the Institute of Actuaries of Great Britain and Ireland and editor of the *Journal of the Institute of Actuaries.*

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Government Shop Hours Bill.

The Government measure to provide for the earlier closing of shops, which was printed on April 29th, has been already met by a hostile motion in the House of Commons from Sir Charles Dilke. This motion is in the following terms: "That in the opinion of this House the proposed measure for the early closing of shops is unduly hampered by restrictions and, not providing for the regulation of the hours of shop assistants, fails to satisfy the terms of the unanimous resolution of this House." In the Bill power is given to the local authority to make an order fixing the hour on the several days of the week at which shops are to be closed. This order must be confirmed by the central authority. Seven o'clock is mentioned as the earliest hour that may be fixed except on one specified day, when it is not to be earlier than one o'clock. The order may prohibit either absolutely or conditionally the carrying on of any retail trade after the closing hour in any place not being a shop within the area under the jurisdiction of the local authority. A number of trades and businesses are scheduled and it is provided that to none of these shall any order apply. The exemptions are post office business, the sale of medicines and medical and surgical appliances, the sale by retail of intoxicating liquors for consumption on or off the premises, the [illegible] refreshments for consumption [illegible] the sale of premises, the sale of [illegible] newspapers, and the [illegible] railway refreshment room. Persons contravening [illegible] be liable to fines varying from £1 to £20.

A Shops Bill Withdrawn.

Lord Avebury's Bill dealing with the Sunday closing of shops came on for second reading in the House of Lords on April 28th but it was withdrawn after a brief discussion. It was contended by Lord Avebury that the opening of shops on Sunday is rapidly increasing. Lord Belper, however, speaking on behalf of the Government, questioned whether a *primâ facie* case had been made out and he backed up this expression of opinion by statistics relating to 1902

In that year there were 5293 prosecutions for Sunday trading and of these 4072 arose in one borough not of [illegible] third [illegible] whole [illegible] local authorities. The inference he drew from these figures was that either over the greater part of the country shops were not open on Sunday or that local authorities did not think it expedient to institute prosecutions. Had Lord AVEBURY resolved to proceed it is very questionable whether he would have obtained a majority for the second reading and in any case there would have been no hope for the Bill in the House of Commons.

Sir Michael Foster and Ventilation.

A feature of a somewhat rambling debate on the domestic affairs of the House of Commons on April 28th was a speech by Sir MICHAEL FOSTER in which he made use of the sentence: "Few things seem to me to want ventilation more than the science of ventilation itself." The debate had turned on the question of the ventilation of the chamber. Sir MICHAEL FOSTER gave it as his opinion that from a chemical point of view the air of the chamber differed very little from the fresh air outside. When they came to regard it from the bacteriological point of view they were dealing with a difficult subject because the knowledge of bacteria was far smaller and less exact than the knowledge of the chemical constituents of air. In the recent investigation he had expected that a larger number of micro-organisms would have been found in the House. Here he interjected a word of warning. "Some of these bacteria are our friends and some are our foes and we do not always know which are our friends. If, therefore, a too zealous committee were to deprive the air of all its micro organisms it is, at all events, possible—I think I might even say probable—that the House would suffer very considerably." And he concluded with an important suggestion. He thought there should be a large inquiry into the whole subject of ventilation, not making experiments upon the House, but using the remarkable circumstances existing there as an example by which to work and to advance the study. Unfortunately, the Commissioner of Works cannot take up the suggestion. He intimated, through his deputy later in the debate, that while he is prepared to allow further bacteriological experiments to continue he cannot find money to make the House the field for extensive scientific investigation.

HOUSE OF COMMONS.

THURSDAY, APRIL 28TH.

The Committee on Nursing.

Mr. SCHWANN asked the President of the Local Government Board what steps, if any, had been taken to deal with the report of the Departmental Committee on Nursing, which was made in November, 1902, and whether the recommendations of the committee in that report were to be adopted as they stand.—Mr. LONG replied: As stated in the reply given to the honourable Member by my honourable friend, the Secretary to the Local Government Board on [illegible], after [illegible] taken in the matter.

Flogging a Boy.

Sir WALTER FOSTER asked the President of the Local Government Board whether his attention had [illegible]

[illegible] the police medical officer, [illegible] of Cruelty to Children, in the sense stated in the [illegible] sed was similar to that used [illegible] istrument is four and a half [illegible] al Government Board with [illegible]

[illegible] as an instrument of punishment shall be abolished and which contains other suggestions with a view to preventing excessive chastisement in future. The action taken by them will, I hope, have the effect desired.

Mr. JOHN O'DONN[illegible] Lieutenant of Ireland [illegible]

[illegible] for vaccination [illegible] and which the [illegible] owing to the number of persons in that union who presented themselves for revaccination,

[illegible] purpose of defraying this charge.

MONDAY, MAY 2ND.

Treatment of Inebriates.

Mr. LLOYD MORGAN asked the Home Secretary whether his attention had been calle[illegible] committed by the magi[illegible] to two years' detention [illegible] the consent of the magi[illegible] home after being detain[illegible] arrested for drunkenness; [illegible] of prohibiting the release of any such offender before the expiration of the term of detention without first obtaining the consent of the magistrate who committed the prisoner.—Mr. AKERS-DOUGLAS replied: Yes, sir, and the facts of the case are as stated in the question. It is much to be regretted that this person, whose [illegible]

[illegible] on the concurrence of the com[illegible] in an equally good position for [illegible] careful conditions might be in[illegible]

Position of Army Nurses.

[illegible] to £350. The pensions depend on the rates of pay and are accordingly increased in proportion.

Irish Poor-law Medical Officers.

[illegible]

Deaths from Burns.

Mr. ARTHUR [illegible] Secretary whether he would give [illegible] aths in the United Kingdom during [illegible] ving resulted from burns caused by [illegible] open fire grates under five years of ag[illegible]

[illegible] formation supplied with the Coroners' [illegible] to procure and the [illegible] could grant would relate only to England and Wales.

State Registration of Nurses.

[illegible] in Poor-law institutions. I am not in a position to give the consent asked for in the question

Unwholesome Teas.

Sir SEYMOUR KING asked the Chancellor of the Exchequer whether his attention had recently been called to the fact that the importation [illegible] Customs regulations over 66,000 pounds of tea were condemned in 1903. I do not think that any alteration in the existing system is required.

TUESDAY, MAY 3RD.

Small-pox in East London.

Sir Thomas Dewar asked the President of the Local Government Board whether in view of the recent outbreak of small-pox in East London he could state to what cause it was attributed and how many patients had been removed for treatment from the various districts of London by the Metropolitan Asylums Board.—Mr. Long replied. I am unable to specify the precise causes to which the outbreak referred to is to be attributed but I may state that several cases occurred in some common lodging houses and seamen's boarding houses in Stepney and Poplar and the earliest of these cases seem to have been those of some cattlemen who came from America. The number of patients removed to the hospitals of the Metropolitan Asylums Board from the various districts of London from March 1st to April 29th was 242.

Fumigation of Vessels.

Sir Thomas Dewar asked the President of the Local Government Board whether he was aware that vessels entering French ports from plague-infected ports were not allowed to load until the owners had had such vessels fumigated for the purpose of securing the destruction of any rats which might be on board; and having regard to the remarks contained in the last annual report of the medical officer of health of the Port of London and the prevalence of plague in the Far East, whether the question of adopting regulations similar to those in force in France would be considered.—Mr. Long said: I am aware of the decree made by the French Government with regard to this matter. That decree was, however, issued before the recent International Conference at Paris took place. The provisions on this subject included in the Convention made as the result of the Conference are less stringent than those of the decree. The Convention is now under the consideration of the Governments concerned. It has been the practice of my department to recommend the destruction of rats on board vessels coming from plague-infected ports when the vessels are empty but it has not been thought necessary to make this compulsory.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, 8, Henrietta-street, Covent-garden, W.C.

Medical Laboratory Methods and Tests. By Herbert French, M.A., M.D. Oxon., M.R.C.P. Lond., Medical Registrar, Guy's Hospital. Price 3*s.* 6*d.* net.

Bale, John, Sons, and Danielsson, Limited, 83–91, Great Titchfield-street, W.

Patent Foods and Patent Medicines. Two Lectures by Robert Hutchison, M.D., F.R.C.P., Assistant Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond-street. Price 1*s.* net.

Diseases of the Appendix Vermiformis and their Treatment. By F. G. Lloyd, M.R.C.S. Eng., L.R.C.P. Lond., late Resident Medical Officer, West London Hospital. Being a Reprint and Enlargement from papers by the same author in The Lancet and *West London Medical Journal*, 1904, and read before the West London Medico-Chirurgical Society. Price 2*s.* net.

Churchill, J. and A., 7, Great Marlborough-street, W.

A Manual of Dental Anatomy, Human and Comparative. By Charles S. Tomes, M.A., F.R.S., F.R.C.S. Sixth edition. Price 12*s* 6*d.* net.

The Closure of Laparotomy Wounds as Practised in Germany and Austria. Including Detailed Methods and Views communicated by over Fifty Leading Surgeons. Edited and translated by Walter H. Swaffield, F.R.C.S. Ed., M.D. Ed., Fellow of the Obstetrical Society of London. Price not stated.

Clay, C. J., and Sons, Ave Maria-lane, E.C.

A Manual and Dictionary of the Flowering Plants and Ferns. By J. C. Willis, M.A., Director of the Royal Botanic Gardens, Ceylon. Second edition, revised and rearranged in one volume. (Cambridge Biological Series; General Editor—Arthur E. Shipley, M.A.) Price 10*s.* 6*d.*

Collingridge, W. H. and L., "City Press" Office, Aldersgate-street, E.C.

The City of London Directory for 1904. Price 12*s.* 6*d.*

Hodge, William, and Company, Edinburgh and Glasgow.

The Medical Inspection of School Children: a Text-book for Medical Officers of Schools, Medical Officers of Health, School Managers and Teachers. By W. Leslie Mackenzie, M.A., M.D., M.R.C.P.E., D.P.H., F.R.S.E., Medical Inspector to the Local Government Board for Scotland, assisted by Edwin Matthew, M.A., M.B., C.M., M.R.C.P.E., Assistant Physician, Leith Hospital; Clinical Tutor, Edinburgh Royal Infirmary. Price 10*s.* 6*d.* net.

Lehmann, J. F., Munich.

Bericht uber 137 Gallensteinlaparotomien aus dem letzten Jahre (6.10.1902 bis 6.10.1903) unter gleichzeitiger Berucksichtigung der nicht operierten Falle. Von Prof. Dr. Hans Kehr in Halberstadt. Price M.5.

Der Einfluss von Boden und Haus auf die Haufigkeit des Krebses, nach Detail-untersuchungen in Bayern. Von Dr.med. Karl Kolb in Munchen. Price M.4.

Longmans, Green, and Co., 39, Paternoster-row, E.C.

The Meaning of a Modern Hospital. By W. Bruce Clarke, M.A., M.B. Oxon., F.R.C.S., Surgeon to St. Bartholomew's Hospital. Price 1*s.* net.

Macmillan and Co., Limited, London.

Notes on the Composition of Scientific Papers. By T. Clifford Allbutt, M.A., M.D., LL.D., D.Sc., F.R.C.P., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge. Price 3*s.* net.

Office of the Superintendent of Government Printing, Calcutta.

Census of India, 1901. [illegible] Report. Volume IA., Part II., Ta[illegible] C.I.E., Officer of the French Aca[illegible] Berlin Anthropological Society, and E. A. Gait, I.C.S., Fellow of the Royal Statistical Society, Anthropological Secretary to the Asiatic Society of Bengal. Price, Part I., Rs.5 or 7*s.* 6*d.*, Part II., Rs.4 or 6*s.*

Rudeval, F. R. de, 4, Rue Antoine Dubois, Paris.

Guide Pratique et Formulaire pour les Maladies de la Bouche et des Dents. Suivi du Manuel Opératoire de l'Anesthésie par la [illegible] Par G. Viau, Chirurgien-Dentiste [illegible]aris, Professeur à l'Ecole dentaire [illegible] Price Fr.6.

University Press, Manchester. Sherratt and Hughes, 59, Long Acre, W.C.

Sketches of the Lives and Work of the Honorary Medical Staff of the Manchester Infirmary from its Foundation in 1752 to 1830, when it became the Royal Infirmary. By Edward Mansfield Brockbank, M.D., M.R.C.P. Price 15*s.* net.

Walter Scott Publishing Company, Limited, London and Newcastle-on-Tyne.

Man and Woman: A Study of Human Secondary Sexual Characters. By Havelock Ellis. Fourth edition, revised and enlarged. Price not stated.

Wiley, John, and Sons, New York. Chapman and Hall, Limited London.

Elements of Water Bacteriology, with Special Reference to Sanitary Water Analysis. By Samuel Cate Prescott, Assistant Professor of Industrial Biology, and Charles Edward Amory Winslow, Instructor in Sanitary Bacteriology in the Massachusetts Institute of Technology. Price 6*s.* 6*d.* net.

A Laboratory Manual of Physiological and Pathological Chemistry. For Students in Medicine. By Dr. E. Salkowski, Professor in the University and Director of the Chemical Laboratory of the Pathological Institute, Berlin. Authorised translation from the second revised and enlarged German edition. By W. R. Orndorff, A.B., Ph.D., Professor of Organic and Physiological Chemistry in Cornell University. Price 10*s.* 6*d.* net.

A Method for the Identification of P[illegible] Systematic Analytical Procedure [illegible] and Chemical Reactions. Vol. I. [illegible] tions of about 2300 of the more import[illegible] with Hydrogen and with Hydrogen and Oxygen. By Samuel Parsons Mulliken, Ph.D., Instructor in Organic Chemistry and Organic Analysis at the Massachusetts Institute of Technology, Boston, Mass. Price 21*s.* net.

Immune Sera. Hæmolysins, Cytotoxins, and Precipitins. By Prof. A. Wassermann, M.D., University of Berlin. Authorised translation by Charles Bolduan, M.D. Price 4*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Birmingham, W. P., M.D. Dub., has been appointed Honorary Consultant to the Fremantle Public Hospital, Western Australia.

Burgess, Mildred M., M.B. Lond., has been appointed House Surgeon to the Royal Free Hospital, Gray's Inn-road, London, W.C.

Clarke, William, M.B. Toronto, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Coventry, Charles, M.B., Ch.B. Vict., has been appointed Officer, Subiaco Local Board of Health, West Australia.

Ellis, L. Erasmus, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., has been appointed Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton, London, S.W.

Falkner, Edgar Ashley, M.B. Durh., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed an Official Visitor for the Hospital for the Insane, Toowoomba, Queensland.

Gow, P., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Surgeon of the Stanley Hospital, Liverpool.

Hayman, Charles Augustine, M.D. St. And., F.R.C.S., L.R.C.P. Irel., L.D.S. R.C.S. Eng., has been appointed Honorary Assistant Dental Surgeon to the Bristol Royal Infirmary.

Hingston, Charles Arthur, M.B., B.Sc. Lond., M.R.C.S., has been re-appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

Hunt, Albert William Dunning, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Chagford District by the Okehampton (Devon) Board of Guardians.

McCash, James, M.B., C.M. Glasg., has been appointed House Surgeon to the Royal Eye Hospital, Southwark.

McEvoy, John Joseph Stuart, M.B. Syd., has been appointed Medical Officer at Beenleigh, Queensland.

Morris, Bedlington Howel, M.B., B.S. Durh., has been appointed Medical Officer of the Adelaide Gaol, South Australia.

Randell, A. E., M.B., B.S. Melb., has been appointed Officer of Health, Victoria Park Local Board of Health, Western Australia.

Robertson, *Monica L. M., M.B.*, B.S. Durh., has been appointed House Physician to the Royal Free Hospital, *Gray's Inn-road*, London, W.C.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

[illegible] at rate of 52 guineas per annum.

BURY ST. EDMUNDS, WEST SUFFOLK GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

[illegible] Salary £[illegible], with board, residence, and washing.

GLASGOW PARISH COUNCIL BARNHILL POORHOUSE, Springburn.—Resident Medical Officer. Salary £250 per annum, rising to £350, with board and lodging.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL, Hastings.—Physician.

INDIAN MEDICAL SERVICE, India Office.—13 Commissions in Indian Medical Service.

[illegible] [illegible]cer. Salary £80 per annum, [illegible]

[illegible] [illegible]PTION AND DISEASES OF THE [illegible], Middlesex.—Surgeon Laryn[illegible]

No[illegible] [illegible]unmarried.

No[illegible] [illegible]E.—House [illegible] Salary at rate of £60 per annum with board residence and laundry [illegible]

[illegible] Resident [illegible] each for [illegible] [illegible]ard, resi[illegible] [illegible] annum, [illegible] Salary [illegible]

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £100, with board, residence, and washing.

ROYAL FREE HOSPITAL, Gray's Inn road, W.C.—Clinical and Assistant Pathologists and Junior Obstetric Assistant (female).

ROYAL LONDON OPHTHALMIC HOSPITAL, City road, E.C.—Third House Surgeon. Salary [illegible]

[illegible] road, N.W.—[illegible] [illegible]dicine. [illegible]s. Salary £90 [illegible]

[illegible] [illegible]edical Officer, [illegible], with board, [illegible]

[illegible] S.W.—House [illegible], [illegible]th board and lodging.

WESTMINSTER GENERAL DISPENSARY.—Resident Medical Officer. Salary at rate of £120 per annum, with rooms, gas, coal, and attendance.

YORK COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTH.

STYLE.—On April 21st, at South Brent, Devon, the wife of F. W. Style, M.R.C.S., L.R.C.P., of a son.

[illegible] [illegible]ch, New Malden, [illegible] daughter of the [illegible], Wallington, by [illegible]er of the bride [illegible]le, father of the bridegroom, and the Rev. J. M. Blake, M.A., minister of the church, John Easton Scott, M.A., M.B., Ch.B. Edin., to Edith Willey, daughter of Mr. and Mrs. John Willey, of Kenley, Surrey.

DEATH.

MICKLE.—Deeply regretted, George Mickle, M.A., M.B., C.M., eldest son of the late Dr. David Mickle, of Kirklington, Yorkshire, on April 20th.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ENTERPRISE.

To the Editors of THE LANCET.

SIRS,—I inclose a copy of a notice recently posted up at the gateway of one of the Central Marine Engine Works, West Hartlepool, and should be glad to hear whether in your opinion the action of the medical gentleman in question is in accordance with professional etiquette. He is engaged in practice in Hartlepool as a "specialist on diseases of the eye, ear, and throat" (the description is his own).

I am, Sirs, yours faithfully,
March 28th, 1904. H. I. L.

[INCLOSURE.]

IMPORTANT NOTICE TO WORKMEN AND APPRENTICES.

A meeting will be held in the Dining Hall on Friday, March 4th, at 5 P.M. prompt.

Business

To move the following resolution:—That the offer of Dr. —— of West Hartlepool *to undertake the treatment of all eye cases* of workmen and apprentices employed in these works at *the rate of 7d. per head per annum be accepted;* and that Dr. —— *be appointed eye specialist on the terms stated above.*

The Doctor's Committee desire a *large* attendance at this important meeting.

The Central Marine Engine Works,
West Hartlepool, 3rd March, 1904.

*** We think that the medical man's enterprise in making such an offer is in doubtful taste. We do not see that he has pursued any courses of study or held any appointments entitling him to style himself a specialist in ophthalmology, otology, or laryngology.—ED. L.

A GARBAGE MONGER FINED.

ON April 28th a butcher named Heileman was fined £20 with £3 3s. costs for exposing diseased meat for sale. In addition to the evidence as to the condition of the meat the suggestion was made on behalf of the prosecution that the meat was destined for the manufacture of sausages, a means of disguise upon the danger of which it is not necessary to dwell. The defence was of a not unusual character in such cases. It was stated that the character of the meat was known (presumably no butcher could have failed to recognise it), but that "by accident" it had not been thrown away.

DESIGN OR ACCIDENT?

To the Editors of THE LANCET.

SIRS,—What makes a young child almost invariably put its first pieces of bread and butter or bread and jam into its mouth with the butter or jam side downwards? You may reply that it is because the child can taste the butter and jam better thus. If that be so, is it the best way perhaps, after all? Or is there any special advantage gained in lubricating the roof of the mouth by eating in the ordinary fashion? I do not think it can be that a certain twist of the hand explains the action of the child.

Perhaps other things can be learned by watching the first actions of children attentively.

I am, Sirs, yours faithfully,
London, April 29th, 1904. TARTINE.

THE PNEUMATIC SADDLE COVER.

WE have received from the Pneumatic Saddle Cover Co., Birkbeck-road, Kingsland, London, N.E., a specimen of their covers which are made to fit over the ordinary bicycle saddle. The cover is easily inflated to the required height by the mouth after it is fixed over the saddle and it is not necessary to use a pump. We have given the cover a trial and find that it forms a very comfortable addition to the ordinary saddle, affording a pleasant feeling of resilience and lessening the ordinary little shocks of the motion of the bicycle. We think that the cover would prove of service to the older generation of bicycle riders, as they would be able to obtain the exercise on which they lay store with less sensation of muscular fatigue. The price of the cover is 3s. 6d.

A NEW SPARKLET SYPHON.

THE sparklet system of aerating water is a great convenience not only to the householder but to the medical practitioner and the best apparatus for the purpose is the recently introduced improved syphon. This has a capacity of about four tumblers. A decided advantage of the method is that water of known purity may be employed, while various medicaments when desired may be added, such as lithium carbonate, piperazine, sodium carbonate, and so forth. The syphon costs only 2s. and the sparklet for charging it a fraction over a penny. It is perfectly simple in construction and the preparation of the aerated water is very easily carried out. The amount of gas contained in one bulb is sufficient to aerate the water and just serves to expel it from the syphon on opening the tap. We find only one drawback to the new syphon and that is that traces of iron, probably from the spout, appear after a time in the aerated water, with the result that on mixing the water with wine or with spirits containing some tannin a slightly inky-looking mixture is formed. It would be a great advantage, though we are aware that it would add much to the cost, if the spout of the syphon were porcelain-lined. The makers are Aerators Limited, Angel-road, Edmonton.

"WHAT IS THE TRICK?"

"ANONYMOUS" writes with regard to the note under this heading in THE LANCET of April 30th, p 1249 "If the baron succeeds in getting the names of any 'distinguished ladies' in an 'interesting' condition, blackmail might easily be the next step. It is possible he suspects a particular lady of being pregnant and adopts this method of obtaining more certain knowledge about her, with a view of blackmailing her in particular." We have received a similar solution from other correspondents.

HOLMAN TESTIMONIAL FUND.

THE following further list of contributions has been forwarded to us by the honorary treasurer of this fund, Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., by whom or by the secretary, Mr. W. A Berridge, Oakfield, Redhill, Surrey, subscriptions will be received:—

	£	s.	d.		£	s.	d.
Mr. R. Clement Lucas	2	2	0	Dr. M. Cecil Hayward (O E.)	1	1	0
Dr. T. Armstrong Bowes	0	10	6	Dr. S. Squire Sprigge ...	1	1	0
Dr. Guthrie Rankin...	2	2	0	Dr. H. M. Stewart	1	1	0
Dr. G. H Savage ...	2	2	0	Mr. Reginald Harrison ...	1	1	0
Dr. Arthur O Latham	2	2	0	Mr. W. Wilson Coltart ...	1	1	0
Mr. Edred M. Corner (O.E)	1	1	0	Mr. E. C. P. Hull	2	2	0

In the list published on April 30th, "Mr. W. D. Cropley" should read Mr. W. D. Crossley.

PEGAMOID WATERPROOF SHEETING.

ACCORDING to the results of a number of tests which we have made with this material it would appear to make an excellent substitute for rubber sheeting in medical and surgical practice. We have tried the effect of various reagents upon it and we find that the material withstands successfully the action of corrosive antiseptics such as carbolic acid, mercuric chloride, ammonia, and, further, the material may be immersed in boiling water without harm. Pegamoid waterproofing has a very clean appearance and it is practically free from objectionable smell. It evidently contains a waxy substance of high melting point, some of which we found is extracted by chloroform. Samples differing in thickness and quality were submitted to us by the New Pegamoid Co., Limited, of 144, Queen Victoria-street, London, E C.

DR. J. T. C. CONRY'S DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Since our last communication, which you inserted in THE LANCET of April 23rd, we have received as under.—

	£	s.	d.		£	s.	d.
Amount then acknowledged	28	12	0	Dr. G. Schorstein	2	2	0
Mr. B. F. Smallman ...	0	5	0	Dr. W. Henry White ...	1	1	0
Dr. Swanton	1	1	0	Total	£33	1	0

We are, Sirs, yours faithfully,

EDWIN T. ENSOR.
WALTER L. ROBERTS.

162, Ladbroke-grove, W., May 3rd, 1904.

THE S. Y. P. PATENT TEAPOT.

THERE have been many modifications suggested in the construction of a teapot all directed towards eliminating as far as possible an excess of tannin in the infusion. The method adopted in the S. Y. P. teapot is certainly one of the simplest. In its normal position the tea-infuser is at the top of the pot and just under the dome. It consists of a small metal cage. Into this the tea is put, the teapot having first been placed in such a position that the tea-infuser is situated perpendicularly and the spout is at the top Hot water is then poured in. After a few minutes' extraction the teapot is put back to its normal position and thus the tea leaves are brought out of the liquid and no further extraction can take place. The design is a successful one and is calculated to obviate the physiologically bad effects due to the drinking of tea containing an excessive amount of tannic acid. The manufacturers are Messrs. J. S. Barwick and Co., 6, Strand-on-Green, Chiswick, London, W.

AN INCOME TAX QUESTION.

To the Editors of THE LANCET.

SIRS,—Please tell me:—I have rooms in town (Manchester) and live outside. If I go by tram car or train or take a cab to my place of work can I set the cost down to my working expenses for income-tax purposes?

I am, Sirs, yours faithfully,

A SURGEON.

*** No.—ED. L.

be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are,—

FOR THE UNITED KINGDOM				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Blood changes.—The characters of the blood are of special interest (*vide* Table III.). The red corpuscles are always reduced in number but rarely to an extreme degree. From two to three millions per cubic millimetre is the common figure and I have never seen a case in which they fell below one million. Fowler records a case in which they were normal in number, but I have never met with such myself. The hæmoglobin is always reduced but not necessarily in proportion to the reduction of red cells, and bearing in mind the low ratio of hæmoglobin which is normal to infancy the percentage may be only slightly reduced. As in all severe anæmias in childhood the red corpuscles are apt to vary a good deal in size, large forms being often met with. More or less of poikilocytosis is usually present, but it is seldom of extreme degree.

Much importance has been attached to the presence of nucleated corpuscles in the blood in this disease. They are certainly usually present but it must be remembered that, as already pointed out, nucleated cells are apt to appear in all severe cases of anæmia in young children and I am not sure that they form a more striking feature in the blood of this disease than in grave secondary anæmias. The majority of them are normoblasts, the nuclei of which often exhibit signs of division, but megaloblasts are also met with. Fowler found them in 13 out of 20 cases and they certainly do not have the same grave significance as attaches to their presence in the blood of the adult. It is difficult to know indeed what importance can be attached to the occurrence of nucleated red corpuscles in the anæmias of childhood. In the cases under consideration at all events they exhibit no constant relation either to the total number of red cells or to the degree of leucocytosis. A reference to the table will show that nucleated red cells may be abundant even although the red corpuscles themselves are not greatly reduced, and a high degree of leucocytosis is not necessarily accompanied by the presence of a high proportion of normoblasts. A leucocytosis is usually present in these cases but not invariably. A reference to the table will show that in a considerable number of cases the total number of white cells is actually reduced. An increase, however, is commoner, but the tendency is to over-estimate it, forgetting that between the ages of one year and 18 months, at which the majority of these cases is met with, the number of leucocytes is normally from 12,000 to 14,000 per cubic millimetre. In order to avoid confusion on this point I have calculated the absolute numbers of granular and non-granular cells per cubic millimetre in each case (see table). It will be observed that in a few cases an absolute increase in the granular cells occurs. In some instances this is undoubtedly due to an ordinary leucocytosis called out by the existence of complications, such as broncho-pneumonia, but in others no such cause could be discovered. More usually the increase is chiefly to be ascribed to an augmented number of non-granular cells in the blood. One can see in this an exaggeration of the normal characters of the blood of infancy and another illustration of the tendency for the adenoid tissue to be affected specially at this time of life. The increase in the non-granular cells tends particularly to affect the larger lymphocytes and the large mononuclears, but every intermediate grade between those and the ordinary small lymphocyte is met with, so that exact differential counting becomes difficult. There is, in fact, a marked polymorphism in the leucocytosis in these cases just as there is in cases of myelogenous leukæmia. Myelocytes are usually present, perhaps in all if carefully looked for. The highest proportion I have seen has been 13·8 per cent. (Case 18); usually they number 2 per cent. They are often small in size and exhibit but sparse granulation. The eosinophiles never appear to be affected but in a few cases I have found mast cells markedly increased. The bearing of the blood changes on theories as to the nature of the disease will be discussed later; meantime it may be pointed out that clinically they are chiefly of importance from the point of view of prognosis. In this respect they afford more trustworthy criteria than any other feature of the disease. The degree of splenic enlargement, for instance, appears to be of little import; on the other hand, the lower the number of red cells and the higher the number of white cells the more severe must the condition be regarded. Further, the more polymorphic the blood—that is to say, the greater the number of large lymphocytes and myelocytes present—the worse is the outlook.

PATHOLOGY.

In proportion to the amount of clinical interest which cases of this group have excited but little attention has been paid to their morbid anatomy and pathology and the descriptions of those who have written upon the subject are mainly confined to the changes met with in the spleen. So long ago as 1886 Stilling[5] described changes in the spleen of rickety children with anæmia, changes which, he said, he had never found in the spleen of an adult. The centres of the Malpighian bodies in these cases showed the presence of areas of epithelial cells of varying size, with protoplasm for the most part homogeneous but containing a few granulations at the periphery and sometimes fat droplets or pigment grains. These cells stained badly and presented a large round or oval nucleus. The mass of lymphocytes surrounding these cells was often so broad as to suggest to this observer an over-activity of the follicle. Sometimes the follicles were very small and not visible at all to the low power but on more careful examination were found to be represented only by small masses of the above cells which had undergone degeneration and vacuolation, the whole appearance giving the impression of a degenerative process. In true cases the follicles are often sharply marked off from the spleen pulp by many concentric layers of densely packed spindle-shaped cells, which form a sort of capsule for the degenerated Malpighian body. Stilling thinks that those appearances indicate an attempt on the part of the spleen to form new cells but that the regenerative elements have undergone degeneration before perhaps they have had time to divide.

Luzet[6] gives a fairly detailed description of the morbid anatomy in one case. He notes in the spleen the existence of perisplenitis but the absence of any increase in thickness of the trabeculæ. The Malpighian bodies were absent but he gives no detailed description of any change in them. He attaches much importance to the absence in the pulp of the large multinuclear cells which he believes to be normally the originators of red corpuscles and concludes from this that the spleen in spite of its size is not taking any active share in the regeneration of the blood. He lays great stress upon the appearance of the liver in his case which presented the fœtal characteristics of indistinct lobulation and showed numerous nucleated red corpuscles between the columns of hepatic cells. Here and there large cells were to be found with nuclei which were often spindle-shaped, exhibited signs of segmentation, and possessed granular protoplasm. These cells he regards as hæmopoietic in nature and on the strength of their presence he considers the essential visceral change in the disease as a resumption of blood-forming functions on the part of the liver. He found the marrow of the femur to be red and rather diffluent. It did not appear to him that the multiplication of red cells in it was very active. Fat was only present in the marrow of the medullary cavity. Mya and Trambusti in a paper published in 1892[7] refer to the changes found by Cardarelli and Fedé[8] and describe the morbid anatomy of two cases of their own. They regard the changes in the spleen as resembling those described by Banti in splenic anæmia—viz., chronic splenitis with hypertrophy of the usual connective tissue of the pulp, much of which had undergone hyaline degeneration. The pulp contained numerous normoblasts with nuclei undergoing mitosis. The Malpighian bodies were atrophic and some of them were converted into mere fibrous knots. The liver in these cases was fatty and they describe the presence in the liver capillaries of multinucleated cells such as those to which Luzet attaches so much importance. They found a great formation of new capillaries in the lymph glands. Fedé,[9] in the joint paper which he wrote with Somma, in dealing with the pathology of the disease stated that the glands were normal or slightly enlarged, that the liver was often enlarged from congestion and that there were slight increase of connective tissue and cloudy swelling; fatty degeneration and atrophy of the liver cells might be present in some cases. The spleen, he said, was very large firm, and dark red on section, its connective tissue was increased, the pulp was rich in lymphatic cells, and the follicles were hyperplastic. Glockner[10] in 1898 described the microscopical characters of the spleen in four well-marked cases of the splenic anæmia of childhood. He summarises his observations thus. There is a varying degree of thickening of the capsule and also of the septa. There is also a general thickening of the reticular framework, forming a network of enlarged and coarse fibres with definite meshes Where this process is most advanced the fibres fuse together into more or less homogeneous bundles There is marked thickening of the adventitia of the smaller arteries in every case and a general anæmia of the whole organ is also striking The Malpighian bodies, apart from thickening of their reticulum, show no marked changes and are well defined The specific elements of the pulp also exhibit in only a few places any real hyperplasia, much more generally some degree of atrophy Only two elements are evidently overgrown—the epithelioid cells of the pulp and, to a less extent, the endothelia of the vessels The former are probably derived from the fixed cells of the connective tissue and as they increase so does the pulp atrophy

Fowler[11] reports upon three cases but remarks that the results do not throw much light on the nature of the disease In one of them the spleen was markedly congested but the Malpighian bodies were distinct and there was a considerable excess of eosinophile cells in the pulp sinuses In a second case the spleen was anæmic, the Malpighian bodies were distinct, and there was an even more marked eosinophilia In the third case the pulp was much hypertrophied and the Malpighian bodies were correspondingly obscured, the condition indeed being not unlike that met with in myelæmia. In this case there was no eosinophilia. In none of the three cases could he find in the liver the hæmopoietic cells to which Luzet attaches so much importance The bone marrow was satisfactorily examined in one case only and appeared to be normal Hunt[12] describes two cases of "splenic anæmia with internal hæmorrhages in infants" In both the spleen was dense, the Malpighian bodies were replaced by fibrous tissue, and the fibrous tissue of the pulp was increased, but not so much as the trabeculæ The enlarged spleen of mere rickets exhibits, he thinks, more change in the trabeculæ and less in the pulp than in these cases, whilst the Malpighian bodies are normal or even exaggerated Ewing[13] in a case of so called von Jaksch's anæmia in a child 20 months old found the pulp cells of the spleen overgrown and the follicles much reduced in size and number Throughout the pulp were numerous collections of small cells with compact or mitotic nuclei Many of these were normoblasts. There was commencing increase of connective tissue and many of the sinuses were obliterated. The liver showed many small intracapillary foci of cells, many of them undergoing mitosis of which the majority were normoblasts, but others were much larger and granular Occasionally they were fused together into a mass resembling the multinucleated masses of Luzet The marrow contained no fat, all its cellular constituents were in a state of hyperplasia. Nucleated red cells were very numerous but eosinophiles were not increased.

I have made careful examinations of the organs in five cases of this disease (Cases 1, 16, 17, and 21 in Table III and in one unrecorded case) The histological changes were neither constant nor identical in all of them In three of them the spleen showed a diffuse overgrowth of the supporting reticulum of the pulp which tended to encroach upon the Malpighian bodies from their periphery so that the outlines of these were lost and in one case at least (Case 16) they were converted into mere knots of fibrous tissue The overgrowth of the pulp stroma in each of these cases was accompanied by thickening of the capsule and trabeculæ of the organ which sometimes reached a high degree In two of the cases, on the other hand (Cases 17 and 21), the Malpighian bodies were large and well defined and there was no overgrowth of the pulp stroma. The pulp spaces were often much congested, but in none of my cases could I find any satisfactory evidence of the resumption of blood forming functions by the spleen nor was there any excess of eosinophile cells present nor any marked overgrowth of the endothelium lining the pulp spaces or venous sinuses.

The marrow was examined both by films and sections in three cases (Cases 16, 17 and 21 in Table III). In every case it was abundant and fleshy and showed evidences of great cellular activity. Neutrophile and eosinophile myelocytes were present in large numbers as well as "lymphocytic" marrow cells but it was difficult to be sure whether these were more numerous than in normal marrow from a child of the same age There was abundant evidence of active red cell formation in all cases but few megaloblasts were observed The liver was examined in four cases In two of these it was practically normal In the others it showed merely fatty degeneration, but in one of an extreme degree I could find no evidence of the presence of Luzet's hæmopoietic cells In none was there any decided increase of the interlobular connective tissue The lymphatic glands were examined in three cases In two of these no change could be discovered In one (No 16) the capsule was much thickened and there was a great overgrowth of the supporting tissue of the reticulum at the expense of the gland parenchyma so that the whole section was solid and fibrous-looking The change was not like that observed in Hodgkin's disease, there being more fibrous tissue formation and less overgrowth of the endothelial cells of the lymph sinuses. It resembled much more the alterations already described as occurring in the spleen pulp in some of these cases.

Speaking generally, the chief change in the spleen in these cases may be spoken of as a chronic splenitis affecting chiefly the pulp but sometimes invading the Malpighian bodies There would seem to be no definite relation between the extent of the spleen changes and the degree of anæmia but the change seems to have gone on to the greatest degree of fibrosis in the cases of longest standing The fatty degeneration of the liver is comparable to that which one finds in all advanced anæmias whilst the condition of the marrow is probably merely compensatory. In the one case in which glandular changes were found the condition seemed to be a chronic adenitis comparable to the chronic splenitis already described

Before proceeding to discuss the relation of the pathological changes to the clinical symptoms in this disease it may be well to indicate briefly the views as to its nature which have been put forward by those who have written on the subject Gretsel[14] writing so long ago as 1866 was the first to apply the term "splenic anæmia" to cases of this group He used the term for convenience and without any theory as to their pathology but simply in order to bring the disease into line with leukæmia splenica and lymphatica as these terms were then used Italian writers early directed their attention to cases of anæmia associated with enlargement of the spleen in infancy Somma[15] in 1884 described a series of cases and applied to them the term "anemia splenica infantile" He was followed by Di Lorenzo[16] who first introduced the term "infective" (infettiva) in connexion with these cases, a term which was subsequently adopted by Somma and by Fedé, Cardarelli, and some other Italian writers who have described cases of this group Most of these writers regarded the disease as due to bacterial infection and describe different forms of micro-organisms found in the spleen which they believed to be the specific cause. Meanwhile von Jaksch[17] described cases of anæmia with splenic enlargement in children which he thought were characterised by reduction of red cells and hæmoglobin, high and persistent leucocytosis, enlargement of the spleen and sometimes of the lymphatic glands and to a less degree of the liver To these cases he applied the term "anæmia pseudo-leukæmica infantum." Von Jaksch's account, probably because it was published in German and at a time when diseases of the blood were beginning to be studied more accurately than ever before, attracted considerable attention and most subsequent writers have followed his terminology To later communications it would be unnecessary and tedious to make any special reference as they add but little to our clinical knowledge of the disease, and the pathological facts which they contain have already been described, but an excellent summary of them will be found in a series of exhaustive papers by Wentworth in vol cxlv of the *Boston Medical and Surgical Journal*. It is to be regretted on every ground that the term "pseudo-leukæmia" was ever applied to these cases by von Jaksch as it has been the means of introducing great confusion into the descriptions of the disease For almost everyone who has devoted special attention to the subject must agree with the conclusion of Wentworth a conclusion which has also been arrived at by the majority of recent writers that the "anæmia splenica infettiva dei bambini" of the Italian writers and the "anæmia infantum pseudo leukæmia" of von Jaksch are

TABLE III.—CASES OF SPLENIC ANÆMIA OF INFANCY.*

No.	Sex and age.	General clinical characters.	Rickets.	Congenital syphilis.	Spleen.	Glands.	Red corpuscles.	Hæmoglobin per cent.	Total white cells per cubic millimetre.	Absolute number of uninuclears per cubic millimetre †	Absolute number of polynuclears per cubic millimetre.†	Differential count (percentages).					Result.
												Polynuclears.	Large mononuclears and transitionals.	Lymphocytes.	Eosinophiles.	Myelocytes.	
1	F., 24 months.	Ill for a few weeks; marked pallor; hæmic murmurs.	Very slight.	(?)	To umbilicus.	Slightly +	1,800,000. Many microcytes and oval forms. No nucleated red cells.	26	1,800	885 (–5715)	887 (–4273)	49·3	7 6	41·6	1·5	—	Died from noma ten months after first coming under observation.
2	M., 12 months.	A twin; always delicate; chlorotic complexion; hæmic murmurs.	Marked head bosses.	–	" "	Definitely +	3,200,000. Unequal in size; some poikilocytosis, a few nucleated.	25	10,920	7469 (–651)	3276 (–2324)	30	68·4		1·5	Very few.	Death from broncho-pneumonia.
3	M., 11 months.	Ailing since bronchitis seven months before; wasted, pale.	Marked.	–	Two fingers' breadth below the umbilicus.	(?)	2,324,000	30	16,000	5280 (–2840)	8960 (+3360)	56	3	30	—	3	Improving when lost sight of.
4	F., 18 months.	Ill since measles three months before; pale but not yellow; hæmic murmurs.	Bossed head.	+	To umbilicus.	–	3,600,000. Some poikilocytosis, a few normoblasts.	32	20,000	14 500 (+7900)	5180 (normal)	25·9	74·3		—	—	Died. No post-mortem examination.
5	F., 13 months.	Very pale; wasted.	+ Head bossed.	(?)	Four fingers' breadth below the costal margin.	Slightly +	2,805,000	33	24,000	10 272 (+2152)	13,800 (+8200)	57·5	10·6	32 2	0·5	6·1	Died from bronchitis three weeks after admission.
6	M., 27 months.	Always delicate; no definite illness; olive complexion.	Moderate.	–	" "	(?)	3,580,000. A few nucleated red cells.	—	15,000	4050 (–1950)	8400 (+3240)	54	11	16	4	5	(?)
7	M., 17 months.	Never well since birth; repeated hæmorrhages; very pale; some purpuric spots.	+	–	Into pelvis.	Very slightly +	3,312,000	28	36,000	20 520 (+13,920)	13,824 (+8664)	38 4	8 6	48·4	0·1	3·5	Improving when lost sight of.
8	F., 9 months.	Wasting and anæmic, one month; following two attacks of diarrhœa and vomiting.	+ Head bossed.	–	To umbilicus.	–	1,040,000	—	34,000	21,030 (+12,950)	12 240 (+6640)	36	4	58	2	(?)	Improving.
9	M., 32 months.	An eight months child; never strong, extreme waxy pallor; hæmic murmurs.	Slight; no bossing.	+	Easily palpable.	–	1,600,000	—	14,000	10,024 (+54.4)	3570 (–1630)	25 5	10·38	61·3	2·7	—	(?)
10	M., 12 months.	Pale and wasting for four months, complexion pale but not yellow, hæmic murmurs	Marked; slight bossing.	–	Half-way to the umbilicus.	–	3,190,000 Not much poikilocytosis; numerous nucleated forms, many of them megaloblasts.	—	35,000	11 900 (+3780)	22 050 (+16,450)	63	14	20·3	0 6	0 6	Died.

11	M, 9 months	Ailing since birth pale, badly nourished, general purpuric rash	Slight, no bossing	(?)	One finger's breadth below the umbilicus	Slightly +	3,700,000	—	18,600	12 210 (+4000)	4625 (−1000)	25	8	66	—	(?)	Died six months later.
12	M, 35 months	Ill off and on since severe diarrhœa six months ago, fairly nourished earthy complexion, hæmic murmurs	None, no bosses	Probable	Two fingers' breadth below the costal margin	—	3 000 000	—	25 000	12 500 (+8000)	10,150 (+5000)	40 6	6	49 4	4	—‡	Improving when lost sight of.
13	M, 18 months	Ailing six months, yellowish complexion, well nourished	+ Moderate bossing	—	One finger's breadth below the umbilicus	Slightly +	2,760 000 No nucleated red cells	—	9 000	2970 (−3600)	5940 (slightly +)	66	33		1	—	Recovered.
14	F, 12 months	Ill two months, sallow complexion, hæmic murmurs	Slight, very slight bossing	—	"	Slightly +	2,750,000	—	52 000	31 720 (+25,120)	14 560 (+9100)	28	7	54	—	7‡	Died
15	M 18 months	Ailing since three months old, prolonged digestive disturbance, pale but not sallow, poorly nourished, slight hæmic murmurs	Moderate	—	Half way to the umbilicus	—	3 085 000 One normoblast to every 100 white cells	—	4,000	1560 (−5000)	2408 (−2700)	60 2	7	32	0 8	—	(?) Recovered
16	M, 36 months	Ill for three months, pale but not chlorotic, fairly nourished, liver enlarged and firm, some ascites	Slight	(?)	Very greatly enlarged	—	2 000 000 Some poikilocytosis, a few normoblasts	40	120,000	95,160 (+88,560)	11 400 (+6240)	9 5	79 3		6	4 2	(?)
17	M 10 months	Wasting since six months old, long standing constipation	Slight	(?)	One finger's breadth below the umbilicus	Palpable in the neck	3 835 000 Marked poikilocytosis, 14 normoblasts to 100 white cells, many showing mitosis	23	15 000	10 500 (+2380)	3780 (−1820)	25 2	18 8	51 2	1 6	3 2	Died from whooping-cough
18	F, 24 months	Ill for six months, chlorotic complexion, liver slightly enlarged	Distinct	+	—	Slightly enlarged all over	4 072 000 Moderate poikilocytosis, normoblasts numerous	32	52 000	31 200 (+24 600)	11 960 (+6300)	23 3	41 3§	18 7	2 8	13 8	Died
19	M, 11 months	A twin, pale since birth bottle-fed, has frequent diarrhœa	Distinct slight bossing	—	Four fingers breadth below the ribs	Slightly enlarged in the neck	1 910 000 Marked poikilocytosis and many normoblasts	34	16 100	8320 (normal)	7280 (+1650)	45 5	52		2 0	0 5	(?)
20	M, 11 months	Co-twin of the above, same history and symptoms	"	—	Three fingers breadth below the ribs	"	3 260 000 Poikilocytosis and many normoblasts	36	18,700	11 220 (+3100)	7106 (+1506)	38	60		—	2	(?)
21	M, 12 months	A seven months child, pale since birth, bottle fed suffers from head nodding	Slight	+	Four fingers breadth below the ribs	—	1 765 000 Poikilocytosis well marked two normoblasts to 100 white cells	26	4 500	2430 (−5690)	1935 (−5665)	43	54		3	—	Died
22	M 13 months	A seven months child, yellowish complexion, general œdema	Slight, head bossed	Probable	Enormously enlarged	(?)	2,585 000 Considerable variation in size, some poikilocytosis, 13 per cent. of normoblasts, many showing mitosis	23	9 350	6002 (−3118)	3459 (−2141)	37	12 5	41	—	9 5	(?)

---

* Since this table was constructed a very similar one has been published by Dr J H Drysdale and Dr Hugh Thursfield in a paper read before the Royal Medical and Chirurgical Society on Feb 9th 1904 As both tables are based largely on the records of the Hospital for Sick Children Great Ormond Street many of the cases included in them are identical † The figures within brackets indicate the absolute excess or deficit of each kind of cell per cubic millimetre calculated on the basis of the normal numbers at different ages, as described in the first lecture ‡ A considerable number with basophile granulation § Most of these were large round cells with diffusely staining nucleus and protoplasm, the latter often with fine basophile granulation, some with mixed granulation

really different ways of describing the same condition. Von Jaksch, in fact, appears to have based his original description simply on a rather severe example of the disease already described by Italian authors. There is thus no real reason for writing as some do of von Jaksch's anæmia as if it were a special morbid entity and the term "splenic anæmia of infancy" is much less objectionable on all grounds than "pseudo-leukæmia infantum" and it is for that reason that I have made use of it in the present description of the disease.

NATURE OF THE DISEASE.

Granted, then, that there exists a clinical group of cases presenting the characters I have narrated and which may be conveniently described under the term "splenic anæmia of infancy," we have next to answer the question: Do such cases constitute a definite morbid entity as clearly marked off from other forms of anæmia as, let us say, myelogenous leukæmia? On the reply to be given to this question different writers hold very different views but they may be divided for purposes of discussion into four groups: 1. Those who hold with Wentworth, Fischl, Morse, and others that the splenic anæmia of infancy is not a definite disease but merely a secondary anæmia which owes its peculiar characteristics to the fact of its occurrence in the early years of life. 2. Those who regard it as merely an aleukæmic stage of a true leukæmia. This view has been specially advocated by Luzet and Troje. 3. Those who consider it to stand half-way between leukæmia and pernicious anæmia, a cross, as it were, between these diseases and partaking of the characteristics of both. This is apparently the opinion of Rotch and Ladd, Engel, and Ewing. 4. Those who consider that the disease is one *sui generis*, which is the position taken up by Alt and Weiss in Germany and by Fowler, Melland, and Drysdale and Thursfield amongst English writers. These different positions must now be briefly discussed.

1. Those who regard the disease as a mere secondary anæmia in which the enlarged spleen is, so to speak, merely an accident, base their position on the absence of any apparent connexion between the blood changes and the splenic hypertrophy. Cases with identical lesions in the spleen—namely, chronic hyperplasia—show varying degrees of anæmia. At times, they say, there are marked changes in the blood and at others the changes are very slight and the degree of leucocytosis shows similar variability. These differences cannot be explained by the duration of the condition in many cases and all that one is justified in saying is that in some of the secondary anæmias of infancy there is a chronic hyperplasia of the spleen and in others not. It may be admitted that many of these statements have much force. There is no definite relationship between the degree of splenic enlargement and the character of the blood in these cases, for the spleen may be very large with slight anæmia or the anæmia may be profound and the splenic hyperplasia by no means excessive. This is by no means so certainly the case as regards the leucocytosis however. I think we can say that there is at least a general ratio between the extent to which the spleen is enlarged and the increase in number of the leucocytes and that these usually vary together. It is the polymorphism of the leucocytosis, however, in these cases which is their most important feature and which distinguishes them, I believe, from the secondary anæmias, just as the polymorphism of the white cells in leukæmia distinguishes that disease from a severe leucocytosis. Even in severe secondary anæmias such as we studied in the last lecture such polymorphism does not occur. Great stress has been laid by the advocates of the view that the splenic anæmia of infancy is merely a secondary anæmia on the association between cases so described with rickets and congenital syphilis. That rickets is a very constant concomitant of these cases may be freely admitted, for all clinical statistics go to prove it. On the other hand, it is equally certain that in a few cases rickets has been absent (Case 12 of Table III.). Nor is there any definite relationship between the severity of the rickets and the degree of splenic enlargement or of blood change. Some of the severest cases show but slight evidence of rickets, whilst severe rickets is often enough accompanied by no appreciable degree of anæmia. Rickets therefore cannot *per se* produce the phenomena characteristic of splenic anæmia and it seems more reasonable to suppose that when the two coexist they are both the result of some common but as yet unknown cause which operates at one time chiefly in the direction of producing anæmia and at others exerts its effects chiefly upon the blood-forming organs.

The evidence in favour of a causal connexion between congenital syphilis and splenic anæmia is even less convincing. The statistics of my own cases showed that the former disease could be excluded in one half the number of the latter and other observers have arrived at very similar results. That congenital syphilis is capable of producing severe secondary anæmia we have already seen and that it can also give rise to splenic enlargement there can be no question, but the latter when due to the syphilitic cachexia is rarely great in degree and is characterised by its occurrence within the first six months of life (Carpenter), a time at which splenic anæmia does not occur. That congenital syphilis, like any other debilitating condition, may predispose a child to become the subject of splenic anæmia one can well imagine, but that there is any more direct relation between them cannot be admitted.

2. The view that the disease under consideration is merely an aleukæmic stage of a true leukæmia—a stage at which the hypertrophy of the spleen is still able to keep in check the excess of white cells produced by the marrow—has been advocated by Troje[13] but has little to commend it. That such aleukæmic stages do sometimes occur in the course of true leukæmias many recorded cases attest, but no one has ever described a case of splenic anæmia in a child which passed later into a genuine leukæmia. Further, it is to be remembered that, as we shall see later, true leukæmia, at least in the myelogenous form, is excessively rare in early childhood, whilst anæmia associated with enlargement of the spleen is by no means uncommon. That being so it is in the last degree improbable that the one is merely a stage of the other. Add to this that the appearances found after death in the two conditions are by no means similar and the proof seems complete that there can be no identity between them. That some of the severest forms of splenic anæmia in infancy do nevertheless suggest, as far at least as their blood picture is concerned, a mild leukæmia cannot be denied, but the appearance is much more that of a mixed myelogenous and lymphatic leukæmia than a pure form of either disease. To this point I shall return, however, when I come to speak of leukæmia in childhood.

3. The view that the so-called splenic anæmia of infancy stands intermediate between pernicious anæmia and leukæmia has not been put forward by its authors with any great degree of clearness. It is difficult especially to ascertain whether they mean to imply by it that these two diseases are actually to be supposed to be coexisting or whether it is merely that the blood picture suggests a mixture of anæmia of these two types. That a casual inspection of a typical blood film from a severe case of splenic anæmia might at first suggest a combination of pernicious anæmia and leukæmia may be admitted but the red cells in this disease are rarely reduced in number to the degree characteristic of pernicious anæmia, and from the mere presence of numerous normoblasts or even megaloblasts in infancy our study of the secondary anæmias showed us that no conclusions can safely be drawn, whilst the supposed resemblance to leukæmia has already been dealt with. Further, the post-mortem appearances are not those of pernicious anæmia. The presence of iron in the liver which is so characteristic of the latter disease is not found in splenic anæmia and to the mere presence of red marrow in the shafts of the long bones no importance can be attached, for, as we have seen, it is a normal occurrence during the earlier years of life, whilst the microscopical characters of the marrow do not at all correspond with those found in true pernicious anæmia. This view may also be dismissed as in no wise helping to elucidate the nature of the disease.

4. We come finally to the only remaining theory—viz., that splenic anæmia of infancy is a definite morbid entity—a disease *sui generis*. The grounds upon which the holders of this view base their opinion have already been considered incidentally when I dealt with the presumption that the disease is merely a peculiar form of secondary anæmia and consist, it will be remembered, in the peculiar type of blood change and, in particular, on the polymorphous character of the leucocytosis. It must be admitted, however, that there is more reason to class these cases by themselves clinically than pathologically, for the splenic anæmia of infancy has no pathological anatomy peculiar to itself. The histological changes in the spleen, though perhaps greater in degree, are still only the same in kind as are met with in many other cachectic conditions, notably in rickets and in congenital syphilis. The changes in the enlarged

---

[13] Berliner Klinische Wochenschrift, No. 12, 1892.

spleen in rickets have been specially studied by Sasuschin[19] in 11 cases. To the naked eye he found that the spleen was firm, its capsule rather thickened, the surface pale, and the Malpighian bodies fewer than normal. The microscope showed a fibrous hyperplasia of the supporting tissue and trabeculæ and thickening of the walls of the arteries. The Malpighian bodies were diminished in size and showed an excess of fibrous tissue at their periphery. Towards their centres groups of endothelial cells, often undergoing degenerative changes, could be made out. The endothelial lining of the blood-vessels was often swollen. He regards the change as one of chronic inflammation which interferes with the function of the spleen as a blood former. It will be noted that these changes are practically identical *with those found in* [illegible] infancy. In the sple[illegible] very similar changes, [illegible] fibrous and the whole [illegible] in amount.

Nor are the changes in other organs any more characteristic. The presence of hæmopoietic cells in the liver which Luzet regarded as pathognomonic of the disease has not been confirmed by other observers and the changes found in the marrow are not sufficiently striking to justify one in regarding them as distinctive. None the less I side with those who would place these cases for clinical purposes in a category by themselves, for diseases cannot be classified entirely on their pathological anatomy, else would chlorosis cease to occupy a chapter by itself in our text-books. That it is difficult to draw any hard-and-fast line between these cases and those of secondary anæmia I admit, for at the lower end of the scale the milder cases merge with those of slight anæmia—usually of a more or less chlorotic type—sometimes met with in pure rickets.[20] At the upper end of the scale we find severe cases which stand, as far as their blood picture is concerned, very close to myelogenous leukæmia though never, I believe, really merging into that disease. It is to these severe cases that the descriptions of the so-called von Jaksch's anæmia specially apply but that they can be sharply distinguished from the milder forms cannot be admitted, for, as the table of cases shows, every intermediate degree of severity is met with. It appears to me that it is better to employ the term "splenic anæmia of infancy" to cover all the cases of every degree of severity rather than to use the description "pseudo-leukæmia infantum" introduced by von Jaksch. For the term "pseudo-leukæmia" is one open to objection on many grounds and has I venture to think been the means of introducing great and regrettable confusion into the whole subject. As to the real causal factor in the disease we are still completely in the dark and I confess I am unable to throw any light on the point. Although enlargement of the spleen seems usually, as a clinical fact, to precede the anæmia, it can hardly be regarded as the cause of the latter, for there is no definite *ratio, as we have seen, between the size of the spleen and the* degree of blood change and in cases which recover the anæmia may pass off long before the spleen has regained its normal size. It would be difficult to understand in any case, as Wentworth has remarked, how a mere fibrous hyperplasia of the spleen could produce by any means an increased destruction of the blood. I am aware that in the so-called splenic anæmia of adults excision of the enlarged organ has often been followed by cure of the disease, but these two disorders, as we shall see immediately, are really entirely distinct and what holds good of one does not necessarily apply to the other. In splenic anæmia of infancy at all events the crucial experiment of operative removal of the spleen is scarcely admissible, for the disease is not one which is inevitably progressive but, on the contrary, is often spontaneously recovered from. On all grounds it seems much more likely that the enlarged spleen and the anæmia are both the result of one common cause, some specific cachexia, possibly toxic in nature. Such a toxin might affect the spleen in the same way as the syphilitic poison does and at the same time induce an increased destruction of red cells or cause an interference with their formation. It has been suggested by Clive Riviere[21] that such a specific toxin as has been postulated may be of gastro intestinal origin and produced by an abnormal growth of micro organisms, the consequence of gastro intestinal catarrh and injudicious feeding. This ingenious hypothesis, however, can hardly be true of all cases, for in a considerable number, at least, one fails to find any history of diarrhœa, whilst, on the other hand, gastro-intestinal catarrh is of such frequent occurrence in infancy that one must always be very chary of assigning *to it a definite share in the production of* any given disease. It should be mentioned, however, that a similar theory has been advanced by Rolleston and others to explain the production of the enlarged spleen of adult splenic anæmia and Hamilton has suggested that the supposed toxin in such cases may owe its origin to an abnormal intestinal flora.[22]

The leucocytosis in this disease may be the consequence of an interference with the function of the spleen, an expression of its physiological incapacity, and an indication of the vicarious performance of its function by adenoid tissue elsewhere, just as happens after experimental removal of the organ. Adenoid tissue elsewhere, acting, so to speak, in a hurry, might easily turn out cells of an immature type such as we have seen to be commonly the case in this disease. It is probable that the changes in the marrow are also of the nature of a compensatory hypertrophy, for if the differentiation of function of the adenoid tissue and marrow is less complete in early life than in the adult it may perhaps be the case that the undifferentiated cells of the marrow in this disease develop into non-granular instead of into granular leucocytes. That the osseous changes in rickets have over-production of marrow as a secondary result is very likely, for we have already seen how closely bone development and marrow formation are related. The head bosses in particular which are so constant a feature in splenic anæmia involve a considerable increase in thickness and extent of the blood forming tissue and may really be as much a hypertrophy of marrow as a bone change.

RELATION OF THE SPLENIC ANÆMIA OF INFANCY TO THE SO-CALLED SPLENIC ANÆMIA OF ADULTS.

I have recommended the use of the term splenic anæmia of infancy to cover all the cases in the group we have just been considering and the only disadvantage of adopting such a nomenclature is that it is apt to lead to confusion with the so-called splenic anæmia of adults. This would be unfortunate, for the two conditions are really entirely distinct. It would be going beyond the legitimate scope of these lectures to discuss whether the splenic anæmia of adults *is a true pathological entity but most people will agree* that the term is at least one of clinical usefulness as covering a group of cases which present a clinical "symptom complex" in common. Many, indeed, would go further than this nowadays and, regarding splenic anæmia as merely the initial stage of what has been described as Banti's disease, would associate with it a constant course and a definite morbid anatomy. The splenic changes in Banti's disease indeed present many points of resemblance to those found in the group of cases peculiar to children which we have been considering. These changes have been summed up as follows:[23] 1. Atrophy of the Malpighian bodies, brought about either by an overgrowth of the connective tissue ensheathing the central artery or by an encroachment of fibrous tissue from the periphery. 2. Thickening of the capsule and the trabeculæ, the walls of the vessels and of the fine fibrous reticulum forming the walls of the spaces of the splenic pulp. 3. In a minority of the cases there is also a proliferation of the endothelium [illegible] ie pulp, the [illegible] large cells [illegible] ed nucleus, the cells in some instances completely filling the blood space.

Here, again, then one finds an overgrowth of supporting

[illegible] is probably due to [illegible] that race. It is [illegible] ed out so long ago [illegible] *rterly Journal* for [illegible] spleen in children [illegible] ave notes of seven cases whose average duration of suckling is 19 months." He adds that these patients are truly chlorotic and invariably exhibit pica.

[21] Transactions of the Royal Medical and Chirurgical Society vol. lxxxvii., 1903.

[22] See discussion on Splenic Anæmia, Brit. Med. Jour., Sept. 12th, 1903.

[23] Trevor: Ibid., Sept. 12th, 1903.

tissue in the Malpighian bodies and throughout the pulp, generally with an increase of fibrous tissue and a proportionate diminution of the adenoid constituents. It must be borne in mind, however, that but little diagnostic importance can be attached to fibrosis involving the trabeculæ and splenic pulp and to atrophy of the Malpighian bodies. As Rolleston[24] has pointed out, varying degrees of splenic fibrosis are met with in long-continued bacterial poisoning and fibrotic atrophy of the Malpighian bodies has been produced experimentally by Pilliet with metatoluylendiamin, paraphenylene, and sodium nitrate. With the morbid histology of the spleen, moreover, the apparent resemblance between Banti's disease or splenic anæmia ordinarily so-called and the splenic anæmia of infancy ceases. The blood picture in the two is totally different. In splenic anæmia of adults we have to deal with a slight diminution of red cells, a marked diminution of hæmoglobin, and a diminished number of leucocytes—a combination described by Senator as oligocythæmia, oligochromæmia, and leucopenia, which contrasts markedly with the great diminution of red cells, the presence of normoblasts, and the heteromorphous leucocytosis characteristic of the infantile disease. In addition to this the clinical course of the disorder is totally different. Splenic anæmia in adults is a very chronic condition which extends over years but is slowly progressive and, so far as we know, invariably leads to death. The splenic anæmia of infancy, on the other hand, is of much shorter duration and by no means progressively fatal but, on the contrary, is recovered from in a considerable proportion of the cases. If, then, these two conditions resemble each other only in the common factor of presenting some degree of anæmia along with enlargement of the spleen the next question which arises is: Does one ever meet in childhood with cases of splenic anæmia of the adult type? Occasionally, I think, one does. Hamill,[25] for instance, has reported the case of a boy, aged six years, who suffered from anæmia associated with great enlargement of the spleen and repeated hæmorrhages. The blood exhibited anæmia of the chlorotic type with leucopenia, but the relative proportion of the granular and non-granular cells varied at different examinations. He died four years later, death being preceded by the appearance of ascites. The necropsy showed fibrous hyperplasia of the spleen and an increase of connective tissue around the bile-ducts in the liver. Hamill does not attempt to classify this case but I think there can be no doubt that it must rank with the splenic anæmias of adult type.

Another case has been recorded by R. T. Williamson.[26] The patient was a boy, aged nine years, whose illness was of two years' duration. There was no evidence of syphilis or rickets. He presented great enlargement of the spleen but not of the lymph glands, with marked anæmia (3,030,000 red cells), and there was no leucocytosis (4000 per cubic millimetre, the lymphocytes being in slight relative excess). There was intermittent pyrexia. He died and the post-mortem examination showed that the Malpighian bodies in the spleen were fibrous, whilst the pulp contained many large cells inclosing red corpuscles. The marrow of the femur was dark red and "lymphoid" and there were some vegetations on the mitral valve and a few ulcers in the small intestine. This case also closely resembles the splenic anæmia of adults but it is difficult altogether to exclude ulcerative endocarditis which seems sometimes to be accompanied by great enlargement of the spleen without any leucocytosis.

In a very typical example of splenic anæmia terminating in Banti's disease described by Rolleston[27] and confirmed by a post-mortem examination the interesting statement is made that the patient, who was 20 years of age, had been an in-patient at the Hospital for Sick Children, Great Ormond-street, for a similar condition 11 years before. Cases of splenic anæmia of adult type do therefore seem to occur in childhood, but owing to the great rarity of that disease even in adult life it is difficult to say with what *degree of relative frequency. As far as I can discover*, however, such cases are not met with in infancy but only after the period of second dentition—that is to say, when the blood has assumed the adult characters. It is true that Hunt[28] has described two cases of splenic enlargement with anæmia in infants aged eight and 16 months respectively which he believes to have been examples of the adult form of the disease but the blood examination is not given in sufficient detail to enable one to form an exact judgment. So far as it goes one of them certainly seems to have been an ordinary splenic anæmia of infancy. It is true also that one meets with great enlargement of the spleen in infancy associated with more or less anæmia but no leucocytosis which present at first sight a resemblance to the splenic anæmia of adults. Examples of these have been given in Table III. There can be little doubt, however, that those are cases of the ordinary splenic anæmia of infancy on the way to recovery, for on following them out one can often find that the spleen gradually recedes behind the ribs until complete recovery is established. Others are probably merely examples of rickets associated with an unusual degree of splenic enlargement. In later childhood again one sometimes meets with puzzling cases in which there is enlargement of the spleen with more or less anæmia but which one hesitates to class as examples of ordinary splenic anæmia of adults. Some of these may possibly be examples of the primary splenomegaly—endothelial hyperplasia of the spleen—so well described by Bovaird,[29] but others are almost certainly of syphilitic origin. To the latter class the following cases probably belong.

CASE 1.—A boy, aged two and a half years, was said to have a lump in the abdomen since he was six months old. There was a definite history of inherited syphilis. He was only slightly anæmic, the red cells numbered 4,500,000, the hæmoglobin amounted to 55 per cent., and the white cells to 13,000 per cubic millimetre. There was a slight relative [illegible] spleen reached below the umbilicus and [illegible] of rickets and a slightly bossed head. [illegible] treatment the spleen rapidly diminished and ten months later had entirely disappeared.

CASE 2.—A boy, aged 11 years, had had an enormously enlarged spleen without other symptoms for upwards of two years. The family history was indefinite but a brother had s[illegible] "bad eyes." *There was no enlargement of the glands or* [illegible] were 4,360,000, hæmoglobin 56 per cent., and [illegible] nuclear and uninuclear forms were about equal. His subsequent history could not be ascertained.

CASE 3.—*A girl, aged 11 years, prese*[illegible] genital syphilis (notching of the teeth, [illegible] spleen was enormously enlarged; the [illegible] The glands were not affected. The re[illegible] normal. The white cells numbered 8000 and a differential count showed 65 per cent. polynuclears, 31·7 uninuclears, and 3 per cent. eosinophiles. She subsequently died rather suddenly when at home.

In the cases cited anæmia was not pronounced but in a series published by Chiari[30] in young adults anæmia was a marked feature and splenic anæmia was closely simulated. In all these cases the *symptoms* appeared to have come on about puberty.

LEUKÆMIA IN CHILDHOOD.

It cannot be said that recent work on leukæmia in the adult has tended to give a sharper definition to our knowledge of the diseases classed under that term or to clarify our notions of their pathology. On the contrary, the division of the leukæmias into two well-defined types which until recently was believed to hold good has been shown to be no longer tenable. The old division into splenic and lymphatic forms, based mainly on clinical differences, had to give way to the pathological classification of lymphatic and myelogenous leukæmia which rested upon the chief kind of cell found in the blood in each case and its supposed seat of origin. But these terms are tending in their turn to lose their applicability as the accumulation of cases and pathological material goes on. It seems no longer possible to speak of lymphatic leukæmia when in some quite typical clinical examples of that form of the disease the only pathological changes have been found in the bone marrow, whilst, on the other hand, the detection of "myelogenous" changes in the adenoid tissue in what seem at the bedside cases of pure myelogenous leukæmia render it difficult to assert dogmatically that this variety of the disease is always due to changes in the marrow alone. It would seem indeed as if the tendency of recent work were to show that the differentiation of function between the bone marrow and adenoid tissue was not so sharp as from the teaching of Ehrlich most people have been inclined to believe, and that in pathological conditions especially a considerable amount of vicarious action can take place in consequence of which the bone marrow no longer confines itself to the exclusive production of granular cells nor the adenoid tissue to the manufacture of non-granular cells and lymphocytes. If this be true of leukæmia in the adult one would expect *a priori* that it would apply with even greater force to leukæmia in childhood, for in the child, as we have already seen, there is reason to suppose that the normal differentiation of function on the part of the marrow and adenoid tissue respectively is less stereotyped than in the adult. We shall see, I think, that this expectation will prove to be correct. It will be convenient to consider first the two extreme and classical types of leukæmia, the myelogenous (so-called) and the lymphatic, and afterwards to glance at the atypical and intermediate forms of the disease.

MYELOGENOUS LEUKÆMIA.

[illegible] ildhood, with [illegible] well-defined [illegible] lults, it is of the most infrequent occurrence in the child and in the period of infancy is hardly met with at all. The statements in text-books on this point which sometimes seem to point to a contrary conclusion cannot be accepted, for they are apt to be based upon cases described prior to the introduction of modern methods of blood examination, many of which in all probability were really examples of lymphatic leukæmia whilst others no doubt belonged to the group of cases already dealt with under the title of splenic anæmia of infancy. The only case I have seen myself was one which was recently under the care [illegible] Hospital and which is to [illegible] resented an extreme and [illegible]

[illegible]

As far as I can discover this is the most marked case of myelogenous leukæmia in a young child yet described. I have collected the following probably genuine cases from the [illegible] 1898, states that the [illegible] less than a dozen in all. [illegible] er seven cases collected by Monti and Berggrun, none of which, however, can one regard as being quite certainly examples of the myelogenous form. Cassel adds an undoubted case of his own. The patient was a boy, aged eight years, who exhibited marked anæmia and great enlargement of the spleen but none of the liver or lymph glands. The blood showed 3,550,000 red corpuscles, 40 per cent. of hæmoglobin, and 500,000 white cells. Of these 69 per cent. were true myelocytes and 12 per cent. were eosinophiles. Polynuclears and mast cells were numerous but lymphocytes were very scanty. The patient was still alive when the paper was published. Baginsky[32] has described an undoubted case in a boy, aged nine years, who presented all the usual clinical features. The red corpuscles amounted to 2,133,000 per cubic millimetre and the white to 986,000. Of these 56·7 per cent. were myelocytes, 26·1 per cent. polynuclears, and 4·1 per cent. eosinophiles. The nuclei of the myelocytes stained deeply with tri-acid mixture and there were as a rule only indications of granules in the protoplasm. The case was lost sight of before its termination. Monti and Berggrun describe a case in [illegible] genuine. He was [illegible] and of rickets and [illegible] 0 and the white to 66,422. [illegible] to 28 per cent. Of the [illegible] large mononuclear forms [illegible] he eosinophiles were also [illegible] and lymphocytes were [illegible] In spite of the small total number of leucocytes in this case it was probably an example of true myelogenous leukæmia. Charon and Gratia[33] describe the case of a girl, aged eight years, who exhibited marked [illegible] and spleen. A [illegible] showed 880,000 [illegible] millimetre, of [illegible] ine examples of [illegible]

pure myelogenous leukæmia in childhood which a fairly complete search of the literature has enabled me to discover,[34] and it will be observed that only one of them belongs to the period of infancy. Even assuming that a certain number have been missed the result fully justifies the statement already made that pure myelogenous leukæmia hardly occurs in early life. This fact in the natural history of the disease is certainly a remarkable one, for there is nothing in the bone marrow in childhood which would lead one to expect that it would be less likely to become the seat of a leukæmic process than the corresponding tissue in the adult, whilst the ease with which myelocytes appear in the blood in early life even in comparatively trivial degrees of anæmia would have prepared one for quite the contrary result. Until we have some definite information as to the true cause of leukæmia no explanation of the rarity of the myelogenous form in childhood is likely to be forthcoming, but it suggests at least that, as is perhaps the case with pernicious anæmia, the exciting cause of the disease is not operative at this time of life.

LYMPHATIC LEUKÆMIA.

When we turn to the so-called "lymphatic" form of leukæmia we are met with quite the opposite state of things. The comparative frequency of this form in childhood is just as striking as the rarity of the myelogenous variety. It is only in quite recent times indeed that the frequency of lymphatic leukæmia has been recognised. McCrae[35] in 1900 described a case and gave references to other 13 cases which had been published as occurring in children below the age of ten years up to that time.

Table IV. contains some of the most important cases in children published since McCrae's summary was made, whilst one meets in the literature with casual references to many others which have never been published in detail. The records of authentic cases, moreover, are being added to almost daily.

Clinically these cases conform to the characters of the acute form of the disease and they may be roughly divided into the three types described by Guinon and Jolly:[36] (1) those which exhibit profound anæmia with general glandular enlargement with a hæmorrhagic tendency in the later stages; (2) those in which the hæmorrhagic tendency is exhibited from the outset, petechiæ appearing early so that the case may resemble one of infective purpura; and (3) "pseudo-scorbutic" cases in which lesions in the buccal cavity are the most striking feature. The type of cell which predominates in the blood is the so-called large lymphocyte, many of which are probably really identical with the "lymphoid cells" of Wolff. Pathologically they show the changes which have been so often described as characteristic of the lymphatic form of leukæmia—viz., overgrowth of adenoid tissue generally with the appearance of foci of it in situations in which such tissue is not normally visible and a replacement of the normal bone marrow by lymphoid tissue.

No satisfactory explanation of the frequency of the lymphatic form of leukæmia in childhood can be given any more than of the rarity of the myelogenous variety. The fact, however, may be correlated with that of the great extent and activity of the adenoid tissue in childhood, to which reference has already been made and which render it peculiarly liable to become the seat of pathological processes of all sorts of which leukæmia is only one form. One is tempted to find in it also some support for the infective origin of the disease which has so often been advocated when one remembers the peculiar liability of children to infection, particularly such as finds access by the throat. On the other hand, those who see in lymphatic leukæmia a process resembling the production of a malignant growth and who speak of it as a "sarcoma of the blood" might point with equal truth to the frequency of that particular form of malignant growth in the earlier years of life. It may be, too, that, as Parkes Weber has suggested,[37] lymphatic leukæmia is to be looked upon as a less differentiated form of the leukæmic process than the myelogenous form of the disease.

TABLE IV.—CASES OF LYMPHATIC LEUKÆMIA IN CHILDHOOD.

No.	Author and reference.	Sex and age.	Total duration.	Clinical characters.	Blood.
1	Thomson and Muir (International Journal of the Medical Sciences, April, 1891).	M., 7 years 11 months.	About 5 months.	Enlargement of the liver, glands, and spleen; general scabies; irregular pyrexia; hæmorrhages.	Red cells, 2,500,000 to 721,250; hæmoglobin 40 per cent.; white cells, 93,000 to 379,000, mainly small lymphocytes; very few polynuclears and eosinophiles; a considerable number of large lymphocytes towards the end.
2	Fowler (Edinburgh Hospital Reports, vol. xiii., 1898).	F., 9 years.	6 weeks.	Extreme anæmia; no enlargement of the spleen or of the glands; hæmorrhage into one retina.	Red cells, 510,000; hæmoglobin 15 per cent.; white cells, 100,000; almost no polynuclears; large and small lymphocytes and large cells with pale, indented nuclei, some with basophile granules.
3	Bradley (New York Medical Journal, vol. lxx., p. 923, 1899).	M., 8 years.	8 ,,	Anæmia; great enlargement of the spleen; slight enlargement of the liver; enlargement of the glands in axillæ and groins; bleeding from the gums.	Red cells, 1,850,000; hæmoglobin, 18 per cent.; white cells, 85,000; polynuclears, 3 per cent.; large lymphocytes, 69 per cent.; small lymphocytes, 28 per cent.
4	Reimann (Wiener Klinische Wochenschrift, No. 39, 1899).	F., 9 years.	6 ,,	The spleen from two to three fingers' breadth below the ribs; slight enlargement of the liver and glands; purpuric hæmorrhages and epistaxis; some swelling of the gums, with bleeding.	Red cells, 1,200,000; hæmoglobin, 20 per cent.; white cells, 350,000; polynuclears predominated at first (mostly eosinophile) but towards the end lymphocytes were in large excess.
5	Pollmann (Munchener Medicinische Wochenschrift, No. 2, 1898).	F., 14 days.	Apparently congenital (mother's blood normal).	Petechial hæmorrhages; the liver and spleen were both much enlarged; right-sided endocarditis; the glands were not enlarged.	Red cells, 2,500,000; white cells, one to eight; almost all uninucleated forms with large nucleus and moderate protoplasm devoid of granules.
6	Guinon and Jolly (Revue Mensuelle des Maladies de l'Enfance, tome xvii., p. 262, 1899).	F., 15 years.	40 days.	Profound anæmia; the liver and spleen were both enlarged (slightly); glands (?).	Red cells, 685,000; hæmoglobin, 20 per cent.; white cells, 28,000; lymphocytes, 93 per cent; polynuclears, from 2 to 3 per cent.; large lymphocytes, from 3 to 6 per cent.; eosinophiles, from 0·1 to 0·2 per cent.; large mononuclears, 0·6 per cent.
7	Geissler and Japha (Jahrbuch fur Kinderheilkunde, Band lii., p. 572, 1900).	M., 5 years.	8 weeks.	Pallor; the glands in the neck and groins were enlarged, not elsewhere; gradual increase in size of the liver and spleen till they reached the umbilicus.	Red cells, 158,000 (lowest count); white cells, 34,250 (highest count); in different counts 76 to 97 per cent. were uninucleated.
8	McCaw (Report of the Society for the Study of Disease in Children, vol. iii., p. 251, 1903).	F., 1 year 8 months.	5	No rickets or anæmia; the spleen was enormously enlarged; considerable general glandular enlargement; the liver was one inch below the umbilicus; subcutaneous hæmorrhages.	Red cells, 2,200,000; hæmoglobin, 39 per cent; white cells, 810,000, of which 99·2 per cent. were lymphocytes.
9	Author's case (unpublished).	F., 6 years.	11 ,,	Profound anæmia; gangrenous stomatitis; irregular pyrexia; the spleen was half-way to the umbilicus; the liver was three quarters of an inch below the costal margin; the glands were palpable all over; petechial and retinal hæmorrhages.	Red cells, 1,200,000; hæmoglobin, 10 per cent.; white cells, 170,000, of which 98 per cent. were lymphocytes (mostly small).
10	Author's case (unpublished).	M., 13 years.	7 months.	The spleen was just palpable; the liver was slightly enlarged; the glands were enlarged everywhere; hæmorrhages from mucous membranes.	Red cells, 2,000,000; hæmoglobin, 40 per cent.; white cells, 240,000, 98·7 per cent. being lymphocytes of varying size; polynuclears, 1·2 per cent.; occasional myelocyte and eosinophile cell seen; one normoblast to 105 white cells.
11	Einhorn (Medical Record, July 12th, 1902).	F., 9 years.	Several months.	The spleen was large and firm; the liver was two fingers' breadth below the ribs; the cervical and inguinal glands were enlarged.	Red cells, 3,360,000; white cells, 389,000, of which small lymphocytes were 48·7 per cent.; large lymphocytes, 49 per cent.; mononuclears, 1·3 per cent; polymorphonuclears, 1 per cent.
12	Carpenter (Brit. Med. Jour., August 29th, 1903).	(?)—3½ years.	4 weeks.	Began with sudden pallor; the spleen was from two to three fingers' breadth and the liver two fingers' breadth below the costal margin; the glands were not enlarged; there were a few bruises on the legs.	Red cells, 1,568,000; hæmoglobin, 15 per cent.; white cells, 130,000, of which 99·18 per cent. were lymphocytes (mainly small).

In other words, we may really be dealing in it with an overgrowth of the original mother cells which are believed to be the progenitors alike of lymphocytes and of the more highly differentiated type of cell known as myelocytes. Lymphatic leukæmia would then be a return to the fœtal stage in which myelocytes have not yet appeared and such a relapse into intra-uterine methods of blood formation may happen more easily in the child than in the adult.

Compared with the acute variety of the disease chronic lymphatic leukæmia is of comparatively rare occurrence in childhood but not more so probably than in adult life. One is met here with the practical difficulty of assigning a limit of duration within which a case shall be regarded as "acute." Any such limits indeed must of necessity be more or less arbitrary in nature. I have met, however, with one case which can be fairly regarded as falling outside the sphere of the more acute type of the disease. It is included in Table IV. (Case 10). Except as regards their duration these cases present no essential difference from those of the more acute form, but the preponderating type of cell in the blood tends to be rather the ordinary small lymphocyte than the larger form of cell met with in the more acute variety of the disease. These cases are chiefly of interest as forming a supposed link between true leukæmia and Hodgkin's disease but to this point we shall return when we consider that disease in detail.

MIXED FORMS OF LEUKÆMIA.

So long as it was believed that the two great seats of production of white cells—the bone marrow and adenoid tissue—were functionally entirely independent and that the former in any circumstances could produce only granular and the latter non-granular cells, so long was it believed that myelogenous and lymphatic leukæmia were two totally distinct conditions which did not coexist and between which no intermediate type was found. But later investigations into the mode of origin of the white cells have rendered it probable that this functional specialism on the part of the adenoid tissue and marrow is not so absolute as had been supposed. It is coming to be believed that both myelocytes and lymphocytes have originally a common parent type of cell and that although it is true that in the marrow the development of these is normally in the direction of producing granular cells (myelocytes) and in the adenoid tissue of producing non-granular cells (lymphocytes), yet upon occasion the parent cells may develop in one direction only in both situations, so that the bone marrow may also produce lymphocytes and the adenoid tissue myelocytes. Coincidently with the rise of this view clinical evidence has been accumulating which points to the actual existence of cases in which the blood presents the picture of a mixed form of leukæmia, both myelocytes and lymphocytes being present in large numbers. Wolff[38] has recently published a criticism of alleged cases of this sort and has come to the conclusion that some of them at least must be regarded as genuine examples of mixed types of leukæmia. Now, as has already been indicated, it is just in childhood when the division of labour between the blood-forming organs is presumably less highly specialised, when myelocytes so readily enter the blood stream, and when lymphocytosis is so common, that one might expect cases of mixed type to occur. Wolff, it is true, declines to admit cases in infancy as affording real evidence of the occurrence of mixed leukæmia because of the confusion and perplexity introduced by cases of the so-called von Jaksch's anæmia already considered. It appears to me, however, to be rather an arbitrary proceeding to rule out such cases. True myelogenous leukæmia is, as we have seen, almost unknown in infancy and it may be that when the disease does occur at this period of life it tends to assume not a pure but a mixed form. Case 16 of my series (Table III.) may perhaps have been of that nature. Morse[39] has reported an interesting case which raises a similar problem. It was that of a boy, one year of age, the exact duration of whose illness was uncertain. He was decidedly rickety and presented enormous enlargement of the spleen with some increase in size also of the liver and lymphatic glands. The blood contained 2,900,000 red cells per cubic millimetre and 48,000 white cells. The differential count showed 23·4 per cent. of small lymphocytes, 8·1 per cent. of large lymphocytes and transitionals, 21·4 per cent. of myelocytes, 46·5 per cent. of polynuclears, and 0·6 per cent. of eosinophiles. There was marked poikilocytosis and many nucleated red corpuscles were present, several of them being megaloblasts. The comparatively low percentage of lymphocytes and the high proportion of myelocytes in this case are certainly unusual even for a severe example of splenic anæmia of infancy, and one is inclined to agree with Morse that the case is rather to be regarded as a mixed form of leukæmia. Fowler[40] has recorded a very similar case in a girl, aged 13 months. There was only slight rickets but the spleen was enormous and the liver and lymph glands were also distinctly enlarged. Purpura and epistaxis were repeatedly observed. Repeated examinations of the blood gave red-cell counts varying from 2,950,000 to 3,950,000 per cubic millimetre, while the leucocytes varied between 23,400 and 58,000. The differential counts varied a good deal, the highest percentage of lymphocytes found being 46. Whilst the myelocytes on one occasion rose to 14 per cent. eosinophiles were not increased. Nucleated red cells were very numerous, nearly all of them being normoblasts. The post-mortem appearances are said to have been those of leukæmia. Fowler regarded the case as one rather of leukæmia than of splenic anæmia from the characters of the blood observed during life. Cabot mentions similar cases.[41] Even were one to admit that these cases are to be regarded as examples of severe splenic anæmia rather than instances of mixed forms of leukæmia the same cannot be said of very similar cases met with at a later period of childhood when splenic anæmia has ceased to occur. Stewart and Campbell[42] have recorded such a case in the person of a boy, aged six years, whose illness lasted only three weeks. He presented marked anæmia, with severe and repeated epistaxis. The spleen was not enlarged but there was some enlargement of the submaxillary glands noted. The blood, which was examined just before death and therefore after repeated hæmorrhages, contained only 750,000 red cells per cubic millimetre with 20 per cent. of hæmoglobin and 40,000 leucocytes per cubic millimetre. Of these 25 per cent. were small lymphocytes, 45 per cent. were polynuclears and the remaining 30 per cent. was made up of myelocytes, 3 per cent. being eosinophilic. The red cells showed considerable inequality in size but none in shape. There were no megaloblasts. A case such as this is obviously very difficult to classify. It is evidently one in which the bone marrow is mainly involved and is so far to be regarded as myelogenous but the high relative number of small lymphocytes would point to some implication of adenoid tissue as well. Another of Fowler's cases[43] is more conclusive. It was that of a girl, five years of age, with enormously enlarged spleen, slightly enlarged liver, and slight hard enlargement of all the superficial lymph glands in whom the illness ran a course of 14 weeks. The red corpuscles were below 3,000,000 and the white corpuscles from 240,000 to 257,000 per cubic millimetre. The differential counts showed: small lymphocytes, 7 to 13 per cent.; large lymphocytes, 32 to 57 per cent.; polynuclears, 16 to 22 per cent.; myelocytes, 12 to 27 per cent.; eosinophile myelocytes, 0·7 to 3·4 per cent.; eosinophiles, 0·6 to 2·6 per cent.; and mast cells, 3 to 3·4 per cent. This seems to be clearly an example of a mixed form of leukæmia and was so regarded by Fowler. Many similar cases could be quoted from the literature[44] but enough has been said to show that the frontiers of leukæmia in childhood are very ill defined. Cases occur intermediate in type between splenic anæmia on the one hand and true leukæmias on the other and also between the two classical forms of leukæmia themselves. Such cases may find an explanation if we regard the myelocytes and the lymphocytes as both arising from a common parent type of cell which we may speak of with Wolff as a "lymphoid" cell, which is probably identical with many of the so-called "large lymphocytes" spoken of in the above differential counts. To this common origin both types of leukæmia could be traced back, myelogenous leukæmia being due to the production from it of myelocytes in excess and lymphatic leukæmia to an excessive production of lymphocytes, whilst in the intermediate forms either the parent cells themselves enter the blood along with myelocytes or both myelocytes and lymphocytes are produced from the common cell in excessive number. The trend of opinion which is supported by such cases as those described is certainly in favour of attaching more importance to the type of cell found in the blood and less to its supposed seat of origin, and if I might venture upon a prophecy it is that in future the leukæmias will be classified on the former basis instead of as hitherto on the latter and that we will speak of myelocytic, lymphocytic, and mixed-cell leukæmias, rather than of myelogenous or lymphatic. At all events, it is only along such lines that order is likely to be introduced into the present confusion which surrounds the classification of those anæmias of children which are attended by a marked increase of white cells in the blood.

[44] Examples of mixed leukæmia in the adult have been published by Simon (American Journal of the Medical Sciences, 125, p. 984, 1903) and by Wilkinson (THE LANCET, June 20th, 1903, p. 1739), but in both of these the case began as apparently one of myelogenous leukæmia and ended by assuming the lymphatic type. Other examples are referred to by Fowler (loc. cit.).

ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE.—A festival dinner in aid of this well-known hospital in Bloomsbury was held on April 27th at Prince's Restaurant, Piccadilly. The Duke of Marlborough presided. A large and distinguished company assembled, including the Duke of Beaufort (president of the hospital), the Duchess of Beaufort, the Marchioness of Lansdowne and the Marchioness of Granby. In proposing the toast of "The King" the Duke of Marlborough said that His Majesty had displayed interest in the hospital by opening one of its wings and had indirectly contributed towards its welfare, as a large annual subscription was received by the hospital from King Edward's Hospital Fund. During the existence of the Alexandra Hospital, which was opened in 1867, many young people had been made healthy and strong who would otherwise have been hopeless cripples. The hospital was in a sense an institution of national importance as the patients came from all parts of the country. It possessed nearly 100 beds and in order to maintain them an expenditure of nearly £6000 a year was entailed. Mr. W. H. Whitfield, the chairman of the committee of management, stated that the income from invested funds amounted to only £300 a year. As a result of the dinner subscriptions and donations amounting to £3600 were announced.

The Erasmus Wilson Lectures

ON

ACUTE INFECTIVE GANGRENOUS PROCESSES (NECROSES) OF THE ALIMENTARY TRACT.

Delivered before the Royal College of Surgeons of England on March 21st, 23rd, and 25th, 1904,

BY EDRED M. CORNER, M.A., M.B., B.C. CANTAB., B.SC. LOND., F.R.C.S. ENG.,
SURGEON IN CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL; ASSISTANT SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE I.

Delivered on March 21st.

MR. PRESIDENT AND GENTLEMEN,—In his presidential address to the Clinical Society of London in 1896 Dr. Buzzard,[1] among other things, discusses whether "those who follow the profession of medicine have no right to speak of their work as science." I should like to point out that through the practice of the art of surgery the surgeon has many opportunities of making numerous scientific observations on man. The subject to which I wish to direct your attention in these lectures is that of acute infective necrosis, or gangrene, of the various regions of the alimentary tract. The life or death of a part of the intestinal canal is one of the greatest importance, especially in abdominal surgery, and through the action of the swift process, already mentioned, are brought about some of the most terrible tragedies in the annals of life.

Every surgeon in the practice of his profession as an operator is in a position to make observations on his cases in a way similar to those which the physiologist and pathologist make on the animals upon which they experiment in the laboratory. Be it, however, clearly understood that the similarities rest on the opportunities and not on the methods. For the surgeon does his work to cure or to alleviate the condition for which his services are required, whilst the others plan their experiments without regard to any benefit which might accrue to the subject thereof. The results of the latter, however valuable, are applied by inference, or indirectly, to man; those of the former have the great advantage of being directly applicable to the subject on which they were made. Every surgeon is in a position to note the results of operations as well as the pathological conditions for which he did the operations. In many cases the results are those of formal procedures and may be of small value, but no one can fail to add to this, especially through the medium of abdominal work, in the way of meeting the unexpected, being the victim of circumstances, mishaps, misfortunes, and lastly, but by no means the least, mistakes. The evidence upon which these lectures are based has been derived in such ways from the study of man during the last five years. And, further, I would like to acknowledge yet again my thanks to the staff of St. Thomas's Hospital for the opportunities of observation which have been so freely accorded me. And rather with the object of emphasising this line of research, which is the peculiar property of the surgeon, I have abandoned the more popular method of experimentation and have performed no operations on animals. But please understand clearly that I in no way under-estimate the very great value of such methods of research. As my observations have been made on the living subject at the operating table I am naturally unable to produce specimens to show; my statements will find evidence in ordinary surgical experience.

THE CLINICAL IMPORTANCE OF ACUTE INFECTIVE NECROSIS IN ACUTE ABDOMINAL WORK.

The death or gangrene of part of the alimentary tract forms one of the most important fields which, by reason of the recent rapid advances, abdominal surgery has taken within its scope. The resulting catastrophes, such as appendicitis, perforations of ulcers, &c., have long been known, as well as the enormous mortality which accompanied them. With increase of our knowledge of the pathology of these cases and improvements in operative technique, the death-rate has of later years been very considerably lowered. Unfortunately, the clinical signs, by means of which we must try to recognise the internal progress of the pathological process are, by their very nature, relatively coarse, late, and inexact means of gaining that urgently required information the possession of which is of vital importance to the patient. The manifestations of an acute abdominal disease are, unfortunately, often very obscure as to their origin, and much valuable time is lost before the decision is made as to whether the abdomen must be opened or not. The tremendous change in the mortality made by such delay is not even yet quite fully appreciated.

All acute abdominal crises begin similarly with shock, collapse, vomiting, &c., which symptoms have been called by Sir Frederick Treves "peritonism." This may be termed the first stage. Later, in the second stage, the diffuseness of the manifestations ceases and localising signs and symptoms appear. But it must be remembered that though the outward appearances become more local the inward infection may be spreading. *At this period a diagnosis may be made.* Later, as the infection becomes more and more diffuse, the signs again become more and more general and the diagnosis is again impossible. It is, in consequence, a difficult task to obtain figures which can give anything like a truthful idea of the practical importance and frequency of the disease which is the subject of these lectures. To help to meet this disadvantage, during the years 1900, 1901, and 1902 a careful record was kept of every acute abdominal case which was admitted to St. Thomas's Hospital. In this way I have obtained a series of 456 consecutive cases quite unique in that the diagnosis was verified in every case by operation or by post-mortem examination. Practically every case came either under the personal observation of my colleague Dr. A. E. Russell or myself. It is our good fortune to be able to place before the medical profession a large and unique series of acute and consecutive abdominal cases spread over a period of three years. The distribution of these cases may be briefly reproduced:—

Table of Acute Abdominal Cases.

Appendicitis	37 per cent.
Intestinal obstruction	24 ,,
Intussusceptions	15 ,,
Perforations	11 ,,
Gynæcological	6 ,,
Peritonitis of unknown origin	2 ,,
The rest	5 ,,

Cases of gangrene or necrosis of the alimentary tract vary considerably in their severity—that is to say, acute, subacute, and more or less chronic clinical varieties are recognisable. As it is the first of these classes to which I wish mainly to direct attention an attempt has been made to estimate the relative practical importance of the pathological factor of acute necrosis in these acute abdominal cases. Briefly, it forms, as a primary process, as in appendicitis, &c., 50 per cent. of these cases and is also secondarily associated with many of the other causes. The large percentage of 50 indicates the great frequency of this necrobiotic process as a primary change, and its occurrence in instances of acute abdominal disease as a secondary change still further emphasises the vast importance of the process. A number of cases are lost and the patients die in consequence of this secondary change, and in abdominal work one must guard against its occurrence just as surely as we try to cure the primary lesion. It is desirable that the full practical import be recognised before the more scientific aspect of the question is touched upon. As a primary affection it may be seen in the perforation of gastric, duodenal, and other ulcers, of carcinomatous ulcers, appendicitis and diverticulitis, &c.; as a secondary process in strangulated herniæ, volvulus, intussusception, strangulation by bands, perforation of the cæcum in intestinal obstruction lower down in the large intestine, &c.

To proceed to its more strict definition the process may be defined as one of death or necrosis of the tissues of the gut, dependent in the acute cases mainly on the action of septic organisms, and in subacute or chronic ones mainly upon the interference with the blood-supply. In the former the organisms act primarily on the tissues, and through inflammation and thrombosis secondarily cause interference with the blood stream; in the latter the blood-supply is interrupted primarily and then the organisms act. Mr. W. Watson Cheyne, in his excellent article in Sir Frederick Treves's "System of Surgery," divides the causes of gangrene or necrosis into three classes—the direct, the indirect, and the specific. But, unfortunately, such a classification can only stand so long as inquiries into it are not prolonged or pertinent. For then is seen the impossibility of dis- [illegible] divisions, I would like to [illegible], two extremes exist: 1. In [illegible] is due to the deprivation of the tissue of blood, aseptic death. 2. In this class the necrosis is due to the action of micro-organisms, septic death. In between these two extremes there exists every variety of mean or intermixture of the factors. The above may, from the point of view of the tissues, be termed the local factors. But the general condition of the individual will take a more or less important secondary part in the process of local death. The flora of the intestines and the fluid of the peritoneal cavity are such that pure anæmic or dry gangrene is unknown there. The omnipresence of moisture and organisms renders the gangrenes in this situation of the moist variety. In reality the tissues of the alimentary tract are subject to the same laws of life and death as are those of the rest of the body and it is my intention to apply to them the above general principles. The branch of inquiry with which this first lecture will deal is the relationship between the integrity of the gut and interference with its blood-supply. Upon this subject surgery has a good deal to say. And an endeavour must be made to reduce the subject into the compass of these lectures. It will therefore be unnecessary to apologise further for any omissions.

---

[1] Transactions of the Clinical Society of London, 1896, vol. xxix., p. 53.

The great clinical difference that is noticed between gangrene or necrosis due to cutting off of the blood supply and that due to activity of bacteria is the different times taken by these factors to produce that result. The former is slow in action, the latter very rapid; and between these extremes there are all varieties of the intermixtures of the factors which are naturally by far the most common and an attempt has been made to investigate the first to begin with and then to pass on to consider the second class.

THE EMBOLISM AND THROMBOSIS OF THE VISCERAL VESSELS OF THE ABDOMEN.

Embolism and thrombosis of the abdominal visceral vessels form an obvious line of inquiry into the nature of the relationship which exists between the integrity of the intestinal wall and interference with the blood-supply. At the first it was my intention to serve up this subject neatly and completely with its literature. But the number of the cases recorded of late has increased so wonderfully that the time has now passed when this would be worth the print and paper, except perhaps in a monograph on the subject. Dr. J. Moyes[2] in 1880 reported on 64 cases; Watson[3] in 1894 collected 27 cases; Deckart[4] in 1902 66 cases; Koebling,[5] also in 1902, 64 cases; but the most extensive is by Gallavardin[6] in 1901 whose zeal enabled him to unearth 126 cases. Since these authors a large number of further examples have been published and a few unpublished ones referred to, so that the actual number will be about 150. With the exception of a few instances, such as those of Elliott,[7] Gordon,[8] and Anfrecht,[9] every reported case has been fatal. Early surgical intervention has saved these; almost all have been reported merely for their pathological interest. It is in the history of most diseases that they are first published as unique pathological curiosities. Slowly [illegible] kindling of [illegible] non disease. [illegible]nce of this history. [illegible]

Looking amongst the reported cases of embolism and [illegible] nd thrombosis it is noticed that some died within 24 hours of the onset of symptoms, some on the second day and others on the third, fourth, and so on. Yet one of Elliott's patients[10] died as late as the twelfth day, one of Kiliani's[11] on the fifteenth day, Munro's[12] on the twenty-second day, and so forth. Some have presented clinical pictures of acute abdominal disease, some of subacute, and some of almost chronic. And yet in all these varieties the diagnosis of embolism has been rendered certain by necropsy. One is forced to wonder, if, after all, spontaneous recovery is not possible in the face of such variations in the length of the illness. In most cases of embolism the clot comes from the left auricle and takes its origin in mitral disease. And, I remember well, when clerking for the late Dr. W. Miller Ord at St. Thomas's Hospital, a little boy with mitral disease who had a sharp attack of abdominal pain and was ill for a few days. The diagnosis made was that of appendicitis, but can it have been that a small embolus lodged in a branch of one of the mesenteric arteries?

Before inquiring into what the pathologists may have to say to this suggestion it is desirable that some account should be given of the important points in the work already done. Blockage of the arteries is more common than that of the veins in the proportion of about 5 to 1. Involvement of the superior mesenteric artery bears as high a proportion as about 40 to 1 to that of the inferior mesenteric artery. This is extremely interesting and the anatomical reasons given for this are like so many anatomical reasons for surgical events, in that they lack perspective and are more or less exaggerated. The real explanation seems to me to be that these statements are made only from a study of fatal cases. For the appreciation of this line of argument it is desirable that a brief description of the anatomical distribution of these mesenteric arteries should be given. The superior mesenteric artery springs from the front part of the aorta, about half an inch below the origin of the cœliac axis and opposite the first lumbar vertebra. It then passes obliquely downwards and forwards in front of the left renal vein, the lower part of the head of the pancreas, and the third or transverse part of the duodenum. Opposite the latter it enters the mesentery of the small intestine, along the root of which it continues to descend, giving off branches into the mesentery to the small intestine from its left and convex side and retroperitoneally to the large intestine on its right or concave side. The branches to the small intestine divide and form four or five arterial arcades, the last of which is within half an inch of the small intestine, and from it straight branches are distributed to the walls of the gut. These straight branches within the gut wall communicate freely with the vessels of the segments above and below. Anatomically the small intestines have wide and excellent blood-supply, expressive of very many alternative routes. On the concave right side of the artery far fewer vessels are given off, thus giving to us an index of, or method of gauging, the severity of the embolic lesion. The first artery to come off is the inferior pancreatico-duodenal, the next is a large branch, the middle colic, then the right colic and the ileo-colic, and finally, the terminal branches to the cæcum and appendix. The main artery as it proceeds diminishes fairly rapidly in size. The embolus may be situated in the main trunk so as to block the inferior pancreatico-duodenal artery, or the middle colic, or the right colic, or the ileo-colic, or the terminal branches. And in each case a corresponding amount of small intestine will have its blood supply cut off on account of the involvement of the corresponding number of the vasa intestini tenuis. The superior mesenteric artery supplies with blood no less than about 25 feet of the length of intestine and is the sole artery to that region. The inferior mesenteric artery supplies the descending colon, iliac and pelvic colon by itself, but the rectum gets no fewer than three arteries, the superior rectal from the inferior mesenteric, the middle rectal from the anterior division of the internal iliac or its inferior vesical branch, and the inferior rectal from the internal pudic branch of the same division of the internal iliac artery.[13]

The duodenum gets its blood-supply from two sources—namely, the hepatic branch of the cœliac axis and from the superior mesenteric artery. The stomach is supplied by the branches of the cœliac axis. The enormous importance of the integrity of the superior mesenteric as compared with that of the other visceral arteries is therefore easily seen, as having manifold the largest and longest distribution it naturally happens that if the main stem is occluded there will be infinitely greater difficulty in the successful establishment of an anastomotic circulation than there will be in the cases of the other visceral arteries which supply smaller lengths of bowel. Anatomically it is seen that nature has been very prolific in supplying means for this end in the anastomotic arcades, &c. Physiologically the case is not so clear. Litten[14] in 1875 showed that in dogs ligature of the stem of the superior mesenteric artery led to necrosis of the small intestine and the death of the animal, whilst he also found that such was not the case when the cœliac artery or the inferior mesenteric artery was occluded. Consequently he argued that though anatomically not an end artery the superior mesenteric was one functionally. Emil Fricker[15] in Berne in 1902 performed a number of ligations of arteries supplying the stomach and duodenum, entirely confirming Litten's results. Hence there seems reason to suspect that lesions of visceral arteries other than the superior mesenteric need not be fatal, and consequently, as our knowledge of the cases under discussion is based solely on post-mortem records, this artery will be found responsible in, to say the least, an undue proportion.

[10] [illegible]

[11] Kiliani [illegible]

[12] Munr[illegible]

[13] The old name [illegible] as been rejected in accordance with Professor Alexander Macalister's suggestion.

The next point which interests us is the evidence for the existence of an anastomotic circulation. First, there is the length of time elapsed after the lodgment of the embolus at which gangrene has been found. Lothrop[16] records the absence of gangrene of the intestine after four and five days have elapsed since the onset of the illness, Osler[17] after seven days, Munro[13] after 22 days, and so on. Secondly, with an embolus in the main trunk of the superior mesenteric artery, practically the whole small gut and the large as far as the splenic flexure may be gangrenous, yet with a precisely similarly situated lesion only a small segment of ileum has been gangrenous after a history of several days' illness (Koster[19]); or in thrombosis of the superior mesenteric vein Bradford[20] found only 18 inches of jejunum gangrenous on the fifteenth day; or, in the case of occlusion of the main trunk of the inferior mesenteric artery only three or four inches of the descending colon were gangrenous on the twelfth day (Elliott[21]), so that there is ample evidence to prove the existence of power to form an anastomotic circulation, which will be successful if the area to be resupplied is not too great, as seems to be the case with blockage of the main trunk of the superior mesenteric artery, though not so when only a branch is involved. So my little boy with mitral disease already mentioned who had an attack of abdominal pain may have had an embolus after all.

The ease or difficulty for the establishment of a collateral circulation is insufficient to account for all the variations found in these cases. Some light as to the possible cause is shown by extremely rapid cases which exhibit an acute infective necrosis of the bowel. For instance, Sievres[22] found incipient gangrene of the gut in a man, 56 years of age, who died within 24 hours of the occurrence of embolism of his superior mesenteric artery. Collier and Burgess[23] record a somewhat similar case. Dr. Frederick Taylor's[24] case died in 30 hours and showed similar necrotic signs, and many other authors have found most extensive gangrene present by the second to the third day. These acute cases are in all probability due to the action of micro-organisms on the tissue of the bowel wall, especially that of pyogenic cocci which have become active on account of the anæmic condition of the bowel brought about by the interruption of the blood-supply. Their absence, or better comparative absence, may account for the subacute cases of longer clinical duration. As yet, however, no bacteriology has been done in these cases. Pilliett[25] has suggested that the thrombosis may have been due to the action of organisms. Pakes's[26] case, in which organisms were found in an ante-mortem clot, renders this suggestion probable. However, the majority of the cases are due to embolism and not to primary thrombosis.

The relationship of the areas of infarction or anæmia and the intensity or degree of the bacterial infection offers an explanation for all the varieties found in the clinical features already mentioned. But that the bacterial factor is not always all-important is shown by the fact that the part of the gut found gangrenous when the superior mesenteric artery is obstructed is almost always that part of the ileum which is about the middle of the area to be resupplied with blood and therefore the last which the anastomotic circulation will reach. And also, the centre of the ileum is not one of the great breeding places for organisms such as the cæcum is, yet the former becomes gangrenous and the latter does not. The formation of an anastomotic circulation is sometimes much impeded by the formation and the extension of thrombi secondary to the embolus. When the occlusion has been slow and the "botanical" condition of the bowels good the collateral circulation will be found to work admirably.

Having now illustrated the formation of an anastomotic circulation in obstruction to the visceral vessels by means of the variations in the time elapsing before the occurrence of the gangrene, the extent of the gangrene, the situation of the gangrene, the immunity with lesions to visceral vessels other than to the widely distributed superior mesenteric artery, &c., some most remarkable cases are brought forward which illustrate the continuation of life after the total obliteration of the visceral arteries. Virchow[27] has reported two cases in which he found post mortem that the main trunk of the superior mesenteric artery had been converted into an impervious fibrous cord. The intestines appeared normal. The clinical records of the previous illness are wanting. Similarly Tiedemann[28] has given an account of a kindred case. Professor Chiene[29] of Edinburgh reported fully a still more remarkable case of a similar and more extensive condition. As the record is in a journal not often consulted by medical men the account is briefly reproduced here. The specimen was found in the anatomy rooms in a female subject who had died from "paralysis" at the age of 65 years. The aorta was extensively atheromatous. There was an aneurysm on the abdominal aorta and the inferior mesenteric artery arose from the lower part of the sac. The cœliac axis arose in its usual position, but for its first half inch was converted into a fibrous cord. The branches beyond this point were fully injected with paint so that there had been established a perfect anastomotic circulation. The occlusion of the trunk of the axis must have robbed the stomach of its entire blood-supply. Presumably the process must have been very slow to enable the second blood-supply to be established without giving rise to any necrosis of the viscus. Both the superior and inferior mesenteric arteries were similarly converted into impervious fibrous tissue close to their origins, their branches being full of the injection of paint. This woman had had the most serious interference possible with the arterial blood-supply of the whole of her alimentary tract, the process of occlusion going on presumably at the same time in each of the three vessels. Yet there were no changes in the intestines such as to call attention to them. Professor Chiene's account of the course of the anastomotic channels is as follows: "This case is probably the *only* recorded example of an obliteration of the three anterior visceral branches of the abdominal aorta at their origins and of a consequent enlargement of the secondary anastomoses for the supply of the viscera, the stomach, liver, spleen, pancreas, and duodenum being supplied by the left lower intercostals and from the left renal and suprarenal arteries which inosculated with the lumbar arteries of the same side, the remainder of the intestines receiving its supply from the internal iliacs through a large plexus surrounding the rectum, except the cæcum and ascending colon which received its blood-supply from the last dorsal artery on the right side." This confirms the existence of a free communication between the visceral vessels insisted on by Sir William Turner[30] in

1863. Professor Chiene's case is much more extensive than either those of Virchow or Tiedemann and therefore has been quoted to illustrate that a properly functional anastomotic blood-supply can be constructed during the slow obliteration of the arteries which supply the alimentary tract from the œsophagus to the anus.

To sum up the chief points which an examination of the records of examples of obstruction of the mesenteric vessels has shown the following tables may be formed:—

CLINICAL TABLE.

1. It is most common in men past middle life.
2. It is most common secondary to valvular disease of the heart, especially mitral disease.
3. The onset is generally sudden with symptoms of peritonism.
4. In one class the picture is one of intestinal obstruction or peritonitis due to appendicitis or the perforation of a gastric ulcer.
5. There is also another class in which blood is passed per rectum and which signifies infarction of the bowel.
6. Subacute and chronic cases are seen as well as the most acute.
7. In some cases it is most probably spontaneously recoverable from, especially if only a small area of the bowel is rendered bloodless.

PATHOLOGICAL TABLE.

1. For a constant situation of the embolus in the superior mesenteric artery as in the main trunk all varieties of clinical cases have been reported, from the most acute and fulminating to cases like Professor Chiene's that recovered apparently without obvious symptoms.
2. With a precisely similar lesion some subjects die in 30 hours and some not for from 12 to 20 days.
3. Gangrene of the gut has been noticed to occur within 30 hours and sometimes not after 22 days.
4. A collateral circulation can be formed in slowly developing cases of visceral vascular obstruction—e.g., Professor Chiene's case. And even in more acute instances an attempt at a collateral circulation is made.
5. The superior mesenteric artery is almost invariably picked out for the site of the embolus in *fatal cases, possibly* because it will always cause symptoms and almost always death, which need not occur with involvement of the inferior mesenteric and its branches or those of the cœliac axis.
6 The explanation of the individual variations, clinical and pathological, seems to depend upon the pathogenicity of the bacteria present in the gut as to the severity, rapidity, or other characters of the cases. On the bacteriology of this affection there is no work done.

[The last two sections of this lecture dealt with the subjects of "Thrombosis of the Mesenterial Vessels of Strangulated Hernia" and "Wounds and Surgery of the Mesentery," in so far as they illustrated the relationship which exists between the integrity of the bowel wall and interference with its blood-supply.]

A COMPARISON OF THE ANIMAL REACTIONS OF THE TRYPANOSOMES OF UGANDA AND CONGO FREE STATE SLEEPING SICKNESS WITH THOSE OF TRYPANOSOMA GAMBIENSE (DUTTON).

A PRELIMINARY REPORT.[1]

BY H. WOLFERSTAN THOMAS, M.D., C.M. McGILL,
J. H. TODD MEMORIAL FELLOW IN TROPICAL MEDICINE,
AND
STANLEY F. LINTON, M.B., B.SC. VICT.,
ASSISTANT DEMONSTRATOR.
(*From the Johnston Tropical Laboratory, University of Liverpool.*)

THE strains we have used in our work are as follows. Three strains of *Trypanosoma gambiense* from Gambia. (See below.) Two strains from Uganda: (1) from the cerebro spinal fluid of a case of sleeping sickness; and (2) from the blood of a case of trypanosome fever. We take this opportunity of thanking Colonel D. Bruce, R.A.M.C., F.R.S., to whom we are indebted for these two strains. Four strains from the Congo Free State: (1)[2] from the cerebro-spinal fluid of a case of sleeping sickness; (2)[2] from the blood of a case of trypanosome fever; and (3) and (4) from the blood of two natives at present under observation in Liverpool.

Trypanosoma gambiense (*Dutton*).—Three strains of *Trypanosoma gambiense* were brought home by Dr. J. E Dutton and Dr. J. L. Todd from their Senegambia expedition[3]; of these three, which are called "Gunjur," "Lammin," and "Q" strains, we have worked almost entirely with the "Gunjur" strain which was derived from the boy at Gunjur, Case 4.[4] Since that time the strain has been passed through a great number of animals under varying conditions; the direct strain is that passed from rat to rat to ascertain whether increased virulence or attenuation of the trypanosomes could be produced. It is not our purpose to present here the results but we believe that a definite increase of virulence as well as an attenuation can be achieved, the former by the passing of the trypanosomes through a large series of animals of the same species and the latter by constantly changing the species of animal employed.

Rats.—Young rats, 30 experiments, shortest incubation two days, longest 35, average from four and a half to seven and a half days. Usual duration from 20 to 41 days. Some have survived 132 days. Adult rats, 33 experiments, from four to 47 days, average eight and a half days. *Duration* from 45 to 388 days. Some rats inoculated in Senegambia in November, 1902, still survive, but their blood is negative microscopically and non-infective. The parasites are present in the blood of both young and adult rats in fair quantities, though in many of the animals they are not constantly present, being at one time numerous in the blood and a few days later absent altogether or only demonstrated after a most careful search.

Mice.—25 experiments. Incubation period from one to 37 days; average from four to seven days. Usual duration from 11 to 14 days. In some cases the parasites have been very numerous and continually present in the blood, but very often the animal shows only a few parasites or there may be a marked irregularity as to the appearance and disappearance of the organisms.

Guinea pigs.—Ten experiments. Three guinea-pigs have become infected after 12, 53, and 73 days respectively and have lived three, four, and eight months. One, Experiment 114,[5] inoculated May 13th and positive 12 days later never showed parasites again in its peripheral blood until Sept. 11th. On Nov. 1st 30 to a field[6] were observed. The trypanosomes continued to increase in numbers and on Dec. 3rd reached 80 to 100 to a field. On the 20th the numbers decreased and death ensued on Jan. 4th. A guinea-pig, Experiment 133,[7] inoculated on July 20th from a rat, was positive on Sept. 11th, parasites became very numerous on Nov. 1st (20 to field), and continued so to the end on Nov. 20th. Rupture of the spleen was the cause of death. Four guinea-pigs inoculated 124 days ago with large quantities of blood containing numerous trypanosomes have remained negative up to the present time despite re-inoculations. Their controls—i e., rats and rabbits—became infected in the usual time. Three guinea-pigs inoculated on March 7th from rat 279a with large doses of blood containing countless trypanosomes showed parasites in their blood in 12 hours in two cases and in three days in the other. The parasites were seen in their blood for a few days (about 24 to a cover). Since March 20th these animals have been negative.

Rabbits.—Incubation period from five to 15 days; average from seven to nine days. Duration from 50 to 128 days. In some cases the organisms have been fairly constant in the peripheral blood, in others they appear and disappear at irregular intervals, and the numbers vary from a few to 20 to a field. In these animals loss of weight and diminution of red cells and hæmoglobin are constant features of the disease. In only one rabbit, which lived 128 days, have we noticed a purulent discharge from the nose, eyes, &c., with loss of hair, and then only in the last six weeks of its existence.

Cats.—Two experiments, both inoculated intravenously.

---

[1] In the forthcoming Johnston and Thompson Yates Laboratories Reports a fuller report will be published together with serum and agglutination experiments and the results of therapeutic experiments.

Experiment 422, inoculated March 12th from a mouse. Trypanosomes were observed on March 19th. Parasites were constantly present, the numbers usually being small. The temperature rose on March 20th to 104·4° F. and on the 22nd to 104·6°. Some loss of weight and anæmia have been observed. Experiment 447, inoculated March 22nd from a rat; positive on March 26th. Parasites were constantly present and in fair numbers—often one to each field. No rise of temperature was observed.

Puppies (from three to seven months).—Three experiments. Incubation periods, five days after intravenous and ten days after intraperitoneal and subcutaneous inoculation. Duration from 33 to 43 days. In two cases the parasites were to be found almost constantly and in fair numbers which increased in the later stages of the disease; before death the blood became negative again. In the remaining experiment trypanosomes were only to be found at intervals and in small numbers. Loss of weight occurred in all three and in two cases there was a marked diminution in the number of red corpuscles with a corresponding decrease in the percentage of hæmoglobin. Subnormal temperature was recorded in one case before death.

Goat.—Small female, Experiment 518. Inoculated intraperitoneally on April 14th from a rat showing numerous trypanosomes. Strain "Lammin." Parasites appeared in the blood on April 21st but have not been found since. No rise of temperature nor other symptoms have yet been observed.

Donkey.—Inoculated subcutaneously on Feb. 23rd from a rat. Positive on March 9th. Parasites were found on rare occasions and then only in very small numbers. There was no definite rise of temperature. Some diminution in the percentage of hæmoglobin and the number of red cells has been observed.

Monkeys.—*Macacus rhesus*, Experiment 311. This monkey had been infected by Dr. H. E Annett with blood from the European Case H. K[8] Parasites were found only at intervals and in small numbers though the animal appeared to be very ill and emaciated; at the end of nine months it had quite recovered. In January, 1904, rats inoculated from it during the preceding four months not having become infected we decided to attempt to reinfect the animal. On Jan. 29th, 13 months after its original infection, it was inoculated with blood from a rabbit ("Gunjur" strain). On Feb. 6th parasites were found in the blood; they were almost always present, though not in great numbers, up to March 24th, from which date until death, on April 3rd, the blood remained negative. Very marked œdema of both upper and lower eyelids, intraorbital space and eyebrows occurred on March 27th; this persisted for three days; no parasites were to be found in the œdema fluid. No other symptoms other than loss of weight and anæmia were observed.

Macacus rhesus, Experiment 517. Inoculated intraperitoneally on April 14th from a rat showing numerous trypanosomes. Strain "Lammin." Parasites appeared in the blood on April 16th. Death occurred on April 18th from purulent and hæmorrhagic peritonitis caused by a parasite found in the intestinal walls and not yet identified.

A chimpanzee, Experiment 134,[9] inoculated by Dutton and Todd in July, 1903. Parasites were rarely seen in the blood and only in small numbers. After the third week in September trypanosomes were found only once in the blood, on Jan. 27th, when one was seen. On this date the temperature rose from its usual level of between 99° and 100° to 103·6° F., falling again next day. Parasites were not seen again before death which occurred from broncho-pneumonia on Feb. 10th.

Sub-inoculations.—Two mice and a rat inoculated on Nov. 20th did not become infected. Of two mice and a rat inoculated on Nov. 27th the mice did not become infected, while the rat was positive once, Jan. 7th, when one trypanosome was found in its blood. Two mice and a rat inoculated with large doses of heart blood immediately after death never became infected.

Symptoms.—There were occasional rises of temperature to 102° to 103° F. with no apparent cause. On one of these occasions (Nov. 27th) one trypanosome was found in the blood. There were temporary loss of weight and appetite and falling off in condition towards the end of December, 1903. The animal subsequently improved and regained appetite. A blood count in July, 1903, showed hæmoglobin 85 per cent. and red cells 8,360,000 per cubic millimetre. One made on Feb. 6th, 1904, showed hæmoglobin 60 per cent. and red cells 4,540,000 per cubic millimetre.

Horse.—Experiment 87. The small bay stallion[10] inoculated in West Africa by Dutton and Todd in February, 1903, and brought to England in July, 1903, is alive and in good condition and seems to have recovered. Trypanosomes have not been seen in its blood since it was brought to England. Two rats inoculated from it at the end of July became infected. Rats and mice inoculated on Oct. 2nd and Nov. 6th have not become infected; and one large rat and two small ones inoculated on April 22nd have not so far become infected. On Oct. 9th, 1903, the weight of the horse was 513 pounds. On April 26th, 1904, it was 506 pounds. The animal shows no symptoms, its temperature is regular (from 99° to 101° F.), and its appetite is good. There is no œdema and its coat is in good condition.

STRAIN DERIVED FROM CEREBRO-SPINAL FLUID OF UGANDA CASES OF SLEEPING SICKNESS.[11]

Rats.—1. Young rats: 12 experiments. Incubation period from four to 13 days; average length nine days. Parasites were fairly constantly present but usually in rather small numbers. Duration from 14 to 41 days. 2. Adult rats: 12 experiments. Incubation period from four to 20 days; average length 13 days. Parasites were fairly constantly present in small numbers in the early stages of infection, later they became rare. Duration from 16 to 149 days.

Mice.—Incubation period from five to six days. Parasites were rarely present in the blood after the first appearance. Duration was from 19 to 47 days.

Guinea-pigs.—Four experiments. None yet infected. Five weeks have elapsed since inoculation. Sub-inoculations into mice and rats so far have been unsuccessful. No symptoms have yet been observed.

Rabbits.—Incubation period from seven to nine days. Parasites are constantly present, tending to become more numerous as the disease advances. Marked and fairly rapid loss of weight is observed. The rabbits are still living. Anæmia is a noticeable symptom.

Cats.—One experiment. A large grey cat was inoculated intravenously from a rat. Incubation was six days. The temperature rose on the evening of the sixth day to 105° F.

Dogs.—One experiment. Inoculated intravenously from a rat showing fairly numerous parasites. Trypanosomes appeared in the blood on the seventh day. The temperature has remained normal. The animal has so far shown no symptoms.

Puppy.—One experiment. Age four and a half months. Inoculated on March 20th from a rat. Trypanosomes appeared in the blood on March 27th and have since been constantly present, although not more numerous than from two to five to a field. The temperature has varied between 101° and 103° F. There was no rise with the appearance of parasites in the blood. Diminution in hæmoglobin and red cells has been observed. The animal has lost strength considerably.

Goat.—One experiment, a female. Incubation period nine days. Parasites were fairly constant in the blood during the first week of infection but afterwards were found only rarely. There was no rise of temperature with the appearance of parasites in the blood but five days later, when eight trypanosomes were seen to the cover, the temperature rose to 104° F. No other symptoms have as yet been observed.

Donkey.—Inoculated on March 28th subcutaneously from a rat. On April 7th the temperature rose to 102·7° F. and on the 9th to 103·2°. A rat inoculated from the donkey on April 8th showed parasites on the 26th. The incubation period in the donkey was therefore ten days. Parasites were seen for the first time in its blood on April 18th and again on the 22nd.

Monkeys.—1. *Cercopitheous callitrichus.* Inoculated intraperitoneally on April 2nd from a rat. Trypanosomes appeared in the blood on the 6th and were constantly present for a week, when they became rare, occasionally being absent altogether. On the 7th the temperature rose to 105·5° F. and has since been irregular (with occasional rises to 104° to 105° and over). No other symptoms have so far been observed, the appetite is preserved, and the animal is in good condition. 2. *Cercopitheous callitrichus.* Inoculated

[9] Dutton and Todd, loc. cit.

[10] Dutton and Todd loc. cit.

[11] This was sent to us in a rat which had been inoculated from a monkey infected from the cerebro-spinal fluid of a case of sleeping sickness; it was therefore only in its second passage.

intraperitoneally on March 6th from a rat showing very few parasites. Trypanosomes did not appear in the blood before death which took place from dysentery on the 10th. A monkey (*Macacus rhesus*), a rabbit, and one out of four rats inoculated with large doses of its heart blood became infected. Two guinea-pigs inoculated at the same time are still negative. Two mice inoculated with its blood died without becoming infected. 3. *Macacus rhesus.* Inoculated on March 10th intraperitoneally and subcutaneously with the heart blood of preceding monkey. Parasites were found in the blood on March 18th and were constantly present, although never very numerous, until April 6th when the animal died. On March 18th the temperature rose to 104·6° with the appearance of parasites in the blood. During the last two days of life the temperature was subnormal (from 95° to 93°). Diminution of red cells and hæmoglobin was observed. Post mortem, purulent peritonitis was found due to a parasite found in the intestinal walls and not yet identified. 4. *Macacus rhesus.* Inoculated on March 14th intraperitoneally with the heart blood of a rat. Trypanosomes appeared in the blood on the 18th and were fairly numerous for four days; on the 31st there were from 13 to 18 to a field. They became rarer again before death which occurred on April 1st. The temperature rose on the 18th and on the 19th reached 105·8°, there being six parasites to a field at the time. The red cells decreased from 4,000,000 to 2,500,000 per cubic millimetre and hæmoglobin from 50 to 27 per cent. 5. *Macacus rhesus.* Inoculated subcutaneously on April 22nd with blood from a rabbit showing many trypanosomes. This monkey is not yet infected (April 27th).

STRAIN DERIVED FROM CEREBRO-SPINAL FLUID OF SLEEPING SICKNESS, CASE 6,[12] IN THE CONGO FREE STATE.[13]

Rats.—23 experiments. Incubation period: young rats from three to nine days; adult rats from four to ten days. Duration from 17 to 176 days. Some of the animals have shown parasites fairly constantly and in moderate numbers; in others the organisms have disappeared for some time or have been present in small numbers. We have rats which have lived as long as 176 days but in the blood of such animals the parasites are either found only in rare instances or not at all.

Mice.—Incubation from four to 11 days. Duration over 92 days. Parasites usually rare.

Guinea pigs inoculated more than 50 days ago have not shown parasites as yet.

Rabbits.—Incubation after intravenous inoculation from three to four days. There was a slight rise of temperature on the day of infection and the following day.

Cats.—Two experiments. 1. Intravenous inoculation from a rat. Incubation period eight days. Parasites were constantly present. On the twelfth day there were five to a field. 2. Intraperitoneal inoculation from a rat. Incubation period eight days. No symptoms have as yet been observed.

Dogs.—Two experiments. 1. An adult dog inoculated intravenously from a rat. Parasites were seen on the fifth day. They were not numerous at first but are increasing and constantly present. 2. A puppy, four months old, inoculated intraperitoneally from a monkey. Incubation period eight days. No symptoms have as yet been observed.

Goat.—An adult, inoculated intraperitoneally from a monkey. The temperature rose on the evening of the fifth day to 106·5° F.; next day the temperature was 104·2°; a rat inoculated on this day is not yet positive. Parasites have not yet been seen in the blood of this goat.

Monkeys.—1. *Macacus rhesus.* Experiment 497. Inoculated intraperitoneally from a rat. Incubation period six days. Parasites have been constantly present in the blood and have steadily increased in numbers. On the day of the appearance of the parasites the temperature rose to 106° F. 2. *Cercopithecus callitrichus.* Inoculated Feb. 15th intraperitoneally from a rat. Parasites appeared in the blood on Feb. 20th. The temperature on the 21st was 103·8° F. Trypanosomes were constantly present in fair numbers until April 5th. Since then they have been rarely found and in only small numbers. No symptoms were observed. The animal was in good condition. There was slight diminution of hæmoglobin and red cells.

STRAINS DERIVED FROM THE BLOOD OF CASE 4[14],[15] AND FROM TWO CONGO NATIVES AT PRESENT UNDER OBSERVATION.

Rats.—Incubation period from four to 11 days, average about seven days; duration, some of the animals have survived after 87 days. In these animals trypanosomes have been scanty in the blood, with periods of some days to even weeks when none were to be found. This perhaps may be accounted for by the fact that the majority of the animals have been direct inoculations from the natives, whereas the sleeping sickness and *Trypanosoma gambiense* strains have been passed through a series of animals.

Mice.—Parasites were always very rare and the duration was indefinite in direct inoculations. In mice inoculated from one of the guinea-pigs sent to us from the Congo Free State (see below) the incubation period was three days and parasites were more frequently present.

Guinea-pigs.—Two guinea-pigs inoculated by us directly from the natives and two young guinea-pigs inoculated from monkeys have been negative for a period of 146 days. Two adult guinea-pigs inoculated from Case 4[15] on the same day by the members of the Congo expedition and sent home while still negative have shown parasites for the first time in their blood on the seventy-ninth and 134th days after inoculation. No symptoms have as yet been observed. They are still living 152 days after inoculation.

Rabbits.—Incubation, direct inoculations nine and 11 days; sub-inoculation from rat ten days. Duration from 21 to 87 days. Parasites have been fairly constantly present but only in small numbers. Loss of weight, slight rise of temperature, and anæmia have been the only symptoms observable.

Monkeys.—*Macacus rhesus.* Two have been inoculated intraperitoneally directly from the natives. Experiment 331. Inoculated on Feb. 9th. Parasites appeared in the blood on the fifth day. On the next day the temperature rose to 104·9° F., the following day it registered 105·8°; at the same time the parasites were observed to increase in numbers. Trypanosomes were constantly present at first. On March 5th there were from 25 to 30 to a field. About the middle of March the trypanosomes became scanty and were not found at all after March 17th. Death occurred on March 25th. Rises of temperature were observed in this monkey coinciding with temporary increase of numbers of parasites in the blood. Experiment 316. Inoculated on Feb. 6th. Parasites appeared on the 13th and at the same time the temperature began to rise and on the 19th it registered 104°; up to the end of March parasites were constantly present in its blood, since that date they have been scanty and sometimes absent. On March 27th marked œdema of the upper and lower eyelids, especially the left, was observed. This persisted for three days; the puffiness was confined entirely to the eyelids; no parasites were found in the œdema fluid. At this time the appetite was poor and the animal seemed to be failing. From April 15th to 22nd parasites were present in fair numbers again, but are now once more scanty. No rise of temperature was associated with this temporary increase. Slight diminution of hæmoglobin and red cells has been observed. The animal is now in better condition than it was a month ago.

STRAIN DERIVED FROM THE BLOOD OF TRYPANOSOME FEVER CASES IN UGANDA.

Rats.—Incubation from 24 to 31 days. Duration from one to four months. This strain was an attenuated one and has died out. Parasites were rarely present and only in very small numbers.

COMPARISON OF SYMPTOMS IN ANIMALS INOCULATED WITH THE ABOVE DIFFERENT STRAINS.

It will be seen that our results have been practically the same whatever the strain used. In rats and mice the same chronic disease, periodicity in appearance of parasites, and absence of symptoms are in all cases observed as were described by Dutton and Todd. M. Brumpt and M. Wurtz have described[16] very marked symptoms in mice and rats inoculated from Congo sleeping sickness cases—e.g., progressive emaciation, intermittent paralysis of the posterior

[16] Brumpt et Wurtz: Maladie du Sommeil Expérimentale, &c., Comptes Rendus de la Société de Biologie, tome lvi., 1904, No. 12, Avril 1er, pp. 567–73.

quarters, œdema of the perineum, and sometimes acute nervous affections. We have observed none of these symptoms; occasionally we have noted slight œdema post mortem, but never in sufficient degree to be detected before death. In guinea-pigs there is with all strains the same lengthy incubation period. In those infected up to the present (with Gunjur and Congo blood strains) there is the same more or less chronic disease, characterised by loss of weight and constant presence of parasites in the blood. In rabbits we have produced with all strains the same chronic disease with fairly constant presence of parasites, loss of weight, and anæmia. In cats the disease is the same with all strains, with rise of temperature on appearance of parasites, fairly constant presence of parasites, and absence of other symptoms so far as we have yet observed. In dogs and puppies there are no differences to be noted. Incubation periods are the same and whatever strain be used there is the same constant presence of parasites in the blood, with loss of weight and anæmia. In goats and donkeys no differences have been observed between the strains used. In monkeys infection is readily produced with all strains, even with very small doses, and parasites are fairly constantly present in the blood, often in considerable numbers. Similar symptoms are observed with the different strains—viz., slight loss of weight, anæmia, rise of temperature especially with the first appearance of parasites in the blood, and occasionally localised œdema. We have observed no marked tendency to sleep in our monkeys; when a monkey is ill it sits on its haunches with its head between its knees; this position, which has been termed the typical sleeping sickness position, is not characteristic of trypanosomiasis or "sleeping sickness"; it is the position assumed by any sick monkey from whatever disease it be suffering. We have noted no nervous symptoms at all.

In stained specimens we have not observed any differences between the trypanosomes of Uganda and Congo sleeping sickness cases on the one hand and *Trypanosoma gambiense* (Dutton) on the other. In the same species of animals and at corresponding stages of the infection the size and appearance of the former trypanosomes are precisely the same as those of the latter as described by Dutton and Todd and since observed by us. In rats inoculated either directly or from monkeys inoculated directly they present the same stumpy and long forms, the former being more numerous in the early stages than in the later. After passage through some generations of rats the stumpy forms show the same tendency to disappear. In rabbits trypanosomes of all strains show the same preponderance of short stumpy forms as compared with rats, mice, and guinea-pigs, while in guinea-pigs, so far as we have yet observed, there is the same greater tendency to length in most of the forms met with. In no animals infected with either the Uganda or Congo sleeping sickness trypanosome have we ever seen any form differing in measurements or appearance from *Trypanosoma gambiense.*

Pathological lesions.—In none of our animals have we found anything differing from the lesions described by Dutton and Todd. Enlargement of the spleen is a feature in all the animals, more especially in rats and mice. In a guinea-pig, Experiment 133 (Gunjur strain), which died 42 days after infection, rupture of the spleen was found, the rupture extending directly across the organ on its upper surface and near the posterior end for about one and a quarter inches. A profuse hæmorrhage occurred and the animal bled to death. No history of an injury is known. Another guinea-pig inoculated with *Trypanosoma dimorphum* (Dutton and Todd)[17] has died from rupture of the spleen. This case will be published in a forthcoming report on *Trypanosoma dimorphum.* The glands are very little, if at all, enlarged and there are no hæmorrhagic glands to be met with as in animals infected with *Trypanosoma dimorphum.* Petechial hæmorrhages are rarely seen. In monkeys the mesenteric glands are enlarged but this is without significance, as all our monkeys were infected with intestinal parasites No macroscopical changes in the nervous system have been noted. In none of our animals, whether allowed to die or killed for special purposes, have we been able to find trypanosomes in the cerebro-spinal fluid, although the blood may have contained many trypanosomes, nor have any of the animals inoculated with this fluid ever become infected.

In the majority of animals which have died we are unable to say definitely that trypanosomiasis was the sole cause of death. Very frequently an intercurrent affection has occurred which, the animal's vitality having become impaired, has caused death. We would instance in rats broncho-pneumonia, caseous lung disease, and enteritis. In rats which have survived a few to many months it is exceedingly rare to find a single parasite,[18] nor has the negative blood appeared to be infective. Experiments are being conducted along these lines. In the majority of cases those rats which have been negative for months die without the presence of trypanosomes being again recognised. In some cases, however, rats which have been negative for months have at death once more shown parasites. As instances of this the following experiments are given.

Rat 95a[19] ("Q." strain) was inoculated on March 17th, 1903, from horse, Experiment 87; incubation period eight days; parasites were found at irregular intervals and in small numbers. On Sept. 13th, 1903, a single parasite to a whole cover-slip preparation was seen and the animal continued negative until its death on March 24th, 1904, 365 days after infection. At the necropsy a few parasites were found in the heart. Animals inoculated from it have not yet shown the infection.

Rat, Experiment 89[20] ("Lammin" strain). Inculated Feb. 26th, 1903, from rat 26; incubation 18 days. Trypanosomes were present in its blood until April 21st. From that time parasites were never seen except on the following dates, July 27th. Sept. 7th, and Nov. 1st, 1903, until its death on March 15th, 1904, 366 days after infection. At the necropsy complete red hepatisation of the whole of the left lung was found. The left pleural cavity contained over five cubic centimetres of slightly yellowish clear exudate containing one parasite to three fields. Animals inoculated with this exudate became infected and from these sub-inoculations we have been able to infect a goat, Experiment 518, and a monkey, Experiment 517.

We have observed that animals with extraordinary numbers of trypanosomes in their blood usually exhibit some lesion which tends to impair their vitality. The following experiment is a good example of this. A rat, 279a ("Gunjur" strain), inoculated on Dec. 30th, 1903, from a guinea-pig became positive on Jan. 7th, 1904 From that time until it was killed on March 22nd the parasites were constantly present in increasing numbers in its blood. At the necropsy caseous lung disease was very far advanced, involving both lungs. Its blood on examination showed trypanosomes in countless numbers. Two rats, two mice, 3 guinea-pigs, one rabbit, and a puppy were all inoculated intraperitoneally with heart blood. 12 hours later the mice and rats, the rabbit and two guinea-pigs were found to be positive, the rats and mice having as many as three to 11 to a field, the rabbit 240 to the cover-slip preparation, and the two guinea-pigs eight to the cover. The puppy did not show parasites in its blood until five days later.

Very little, if any, immunity is conferred by infection with *Trypanosoma gambiense.* The two following experiments are of interest in this connexion.

1. A piebald rat was inoculated directly from Mr. Q. by Dutton and Todd on Nov. 3rd, 1902. Parasites were found in its blood on Nov. 12th and again on Feb. 27th, 1903. After this the blood was always negative. On Nov. 23rd, 1903, it was reinoculated intraperitoneally from a rat ("Gunjur" strain) showing very numerous trypanosomes. It became infected and on Dec. 9th its blood was swarming with trypanosomes. Death took place on Dec. 26th.

2. A monkey (*Macacus rhesus*) infected by Annett from H. K., (Dutton's original case) in 1902 recovered, its blood being *non-infective* to rats. On Jan. 29th, 1904, it was reinoculated (Experiment 311), from a rabbit ("Gunjur" strain) and became infected (see above).

As one would expect, there is no transmission of immunity to offspring. Several of the young rats which we have infected have been born from parents which either were infected at the time or had recovered from an infection. And one guinea-pig (Experiment 216) which we infected with "Gunjur" strain was born from a guinea-pig infected at the time (also with "Gunjur" strain). There is a certain amount of natural immunity or resistance to the human trypanosome to be met with in individual rats and other animals. Every now and then we have come across animals which have exhibited this feature. For example, of two rats A and B of the same size, inoculated at the same time with equal amounts of virulent blood from an infected animal, A will become infected while B remains uninfected or shows a prolonged incubation period. Again, A receives a larger dose than B; it frequently happens that B will show the infection earlier than A. Guinea-pigs show considerable resistance to infection. As instances of this we would mention those inoculated from Rat 279A (see above). Baboons (*Cynccephalus sphinx*) have up to the present been absolutely refractory.

CONCLUSIONS.

1. The trypanosomes found in (*a*) cerebro-spinal fluid of Uganda sleeping sickness cases, (*b*) cerebro-spinal fluid of Congo Free State sleeping sickness cases (*c*) blood of Uganda trypanosome fever cases, and (*d*) blood of Congo Free State trypanosome fever cases, are all identical in animal reactions and morphology with *Trypanosoma gambiense.* The specific name *gambiense* (Dutton) must therefore for the future include the trypanosomes from the above-mentioned sources.

2. There seems to be no acquired immunity against infection.

3 There is no transmission of immunity to offspring.

4. An animal which seems to have recovered may months later show parasites once more, apparently as the result of lowered vitality.

YEOVIL HOSPITAL.—A new operation theatre at this hospital, erected at a cost of over £1000 as a memorial of the King's accession and the restoration of peace in South Africa, was formally opened on May 4th by the Hon. Mrs. Arnold de Grey in the presence of a large gathering.

A CHINESE REMEDY FOR HYDROPHOBIA.

BY VIDAL G. THORPE, M.R.C.S. ENG., L.S.A. LOND.,
FLEET SURGEON, R.N.

SOME time ago I was told of a remedy for hydrophobia which was used by the natives in this part of China. It was said to be a secret in the sole possession of one family whose ancestral home is Tungchow Foo in the province of Shantung, and had been passed down from mother to daughter for the last 400 years. The last possessor of the secret had no daughters and revealed it to her youngest son who now lives in Wei-Hai-Wei. The remedy was said to consist of a powder made from a certain hard nut grown in the province which was softened by boiling in an earthenware pot, no kind of metal being allowed to touch it, then grated on the outside of the basin and reduced to a pulp, which was dried and put up in packets for future use, or at once administered to the sufferer who, if necessary, was tied down and the remedy forced down his throat. The patient was said to fall into a deep sleep, in which he sweated profusely and awoke cured. No money was taken in payment, the possessor of the secret trusting to gain merit in the next world after death. I was assured that cures were authentic; my informant, a Scotch lady, who had lived many years in China, had a Chinese servant who was bitten by a mad dog and was treated and recovered; a woman, bitten at the same time not treated died with all the symptoms of hydrophobia. My friend, at my request, very kindly managed to procure me an interview with the owner of the secret, who brought me his basin and three powders and three nuts. I was astonished to find that they were the seeds of a species of strychnos, probably strychnos nux vomica. The coarsely ground fibrous powders gave the tests, as far as I was able to carry them out, for strychnine. Each nut was about five-eighths of an inch across and weighed 19 grains. The powders weighed 14, 15, and 16 grains respectively. It would be interesting to know what the exact dose of the alkaloid in each powder is. The proportion, I believe, as a rule varies between 0 2 and 0·5 per cent., which would give from $\frac{1}{33}$rd to $\frac{1}{13}$th of a grain of strychnine in each powder.[1]

I can find no account of the treatment of hydrophobia by strychnine in the books at my disposal, unless we except curara which was at one time used as a remedy in this terrible disease; a species of strychnos is said to be a potent element in its composition. The narcotic and sudorific properties spoken of above seem also to be unknown at the present time, yet curiously enough the writer of the article "Nux Vomica" in "Chambers's Cyclopædia" of the year 1786, the four volumes of which I possess, lays greater stress on these than he does on its poisonous properties. He states that "they are of a strong narcotic quality so as to be ranked in the number of poisons." After describing the round, flat, grey, mouse-coloured seeds he states that "Hermannus, botanic professor at Leyden, who has written expressly on it, says that the *vomic nuts* of Timor and Ceylon are for the human species excellent sudorifics, and are also to be ranked among diuretic medicines. Fallopius relates that it was given with success in the plague; that in doses from a scruple to half a drachm it procured a plentiful sweat, in which case the patient recovered." But no mention of its use in hydrophobia is made in this article nor in the one devoted to the description and treatment of that disease. I have also consulted several authorities on China and though the drug certainly finds a place amongst native medicines I can find no reference to its use in this disease nor that it is at all used by native practitioners, at least in this part of China. Some of the symptoms of hydrophobia bear a certain resemblance to those of poisoning by strychnine and it would therefore almost appear as though the principle of *similia similibus curantur* has been applied by the Chinese in this case. There is no doubt that in regard to other remedies they have a firm belief in this doctrine.

Wei Hai-Wei, China.

---

[1] Fleet Surgeon Thorpe inclosed one uncrushed seed and one crushed. The powdered nut weighed 0 925 gramme and the uncrushed nut 1·270 grammes, the total weight being 2·195 grammes. The two when extracted gave 2 60 per cent. of mixed alkaloids. Allen states: "The alkaloids in powdered commercial nux vomica ranged from 2 56 to 3 57 per cent." The alkaloids extracted gave the characteristic reaction of brucine and strychnine, the former being in decided excess.—ED L.

ALIENS, DIRT, AND DISEASE.

BY N. BISHOP HARMAN, M.A., M.B. CANTAB., F.R.C.S. ENG.,
OPHTHALMIC SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN; CHIEF CLINICAL ASSISTANT, ROYAL LONDON OPHTHALMIC HOSPITAL; DEMONSTRATOR OF PATHOLOGY IN THE MIDDLESEX HOSPITAL; LATE EXAMINER, NATURAL SCIENCES TRIPOS, UNIVERSITY OF CAMBRIDGE.

IN the debate on the Aliens Bill in the House of Commons on April 25th the Right Hon. James Bryce is reported as saying "that evidence and statistics alike went to show that Russian and Polish Jews were generally healthier than English workers, especially in regard to contagious diseases."[1] I notice that Mr. Bryce is reported in the same terms by the *Daily Mail*; since such redoubtable antagonists as the *Daily Mail* and the *Daily News* are agreed on the matter we may take it that Mr. Bryce did utter this opinion. Recently I have made an investigation into the influence of such factors as age, sex, and social conditions on the incidence of disease of the eye. I shall here give my results as far as the influence of social conditions is concerned.

ALIENS AND NATIVES.

By the permission of Mr. W. T. Holmes Spicer I have examined all the letters of new patients attending his clinic at the Royal London Ophthalmic Hospital for the year 1902. The clinic is one of 12 and it is held on Wednesdays and Saturdays. On Wednesdays the proportion of alien patients to native is 1 in 30 and on Saturdays it rises as high as 1 in 3. The patients numbered 2751. Of these I find 2124 were natives and 627 were aliens. The separation was made by the indication afforded by the names of patients, experience teaching one to distinguish readily alien names; doubtful cases were classed with natives, so that this allowance and the known tendency of aliens to adopt local names imply that the number of aliens has been rather under-estimated. The classification of the patients stands thus:—

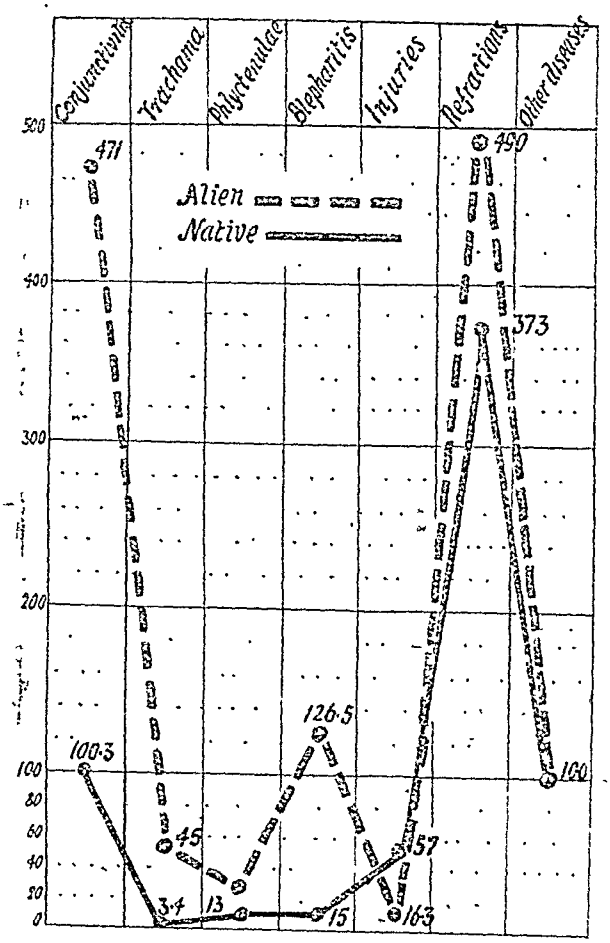
Condition.	Native.	Alien.
Conjunctivitis	321	231
Trachoma	11	22
Phlyctenulæ	42	14
Blepharitis	48	63
Injuries	180	8
Refractions	1202	240
Other diseases of eye (lens, uvea, &c.) ...	320	49

These figures suggest at a glance that aliens suffer more from inflammatory conditions than do natives. The comparison may, however, be made more emphatic by the following procedure. In comparing the incidence of disease in age and sex it was found impossible directly to compare results owing to the disturbing influence of refraction cases which fall particularly heavy at certain periods of life. A "constant" was needed, some disease or group of diseases having a uniform incidence under all conditions of age, sex, or other factor. This "constant" I found in the group marked "Other diseases." The group is a heterogeneous mixture of cases that occur throughout life or in infancy, in youth, or in age alone—lenticular, uveal, fundus, or congenital cases having no connexion with conjunctival conditions—yet despite the mixture in the quality of the cases in the mass they make a fair balance of quantity for each year of life. There is no reason to suspect any racial variation in the incidence of this group of diseases. The same "constant" has therefore been taken for the comparison of the above figures and it will be shown later that the method stands the severest possible test. The results of this comparison are set out graphically in the chart.

---

[1] *Daily News*, Parliamentary Reports, April 26th.

The alien suffers from conjunctivitis, trachoma, and blepharitis very much more than does the native, even from five to 12 times more. All these diseases are contagious, some are epidemic, and others endemic. Only in the matter of injuries to the eye by accidents, trivial or serious, is the incidence less in the alien than in the native; this is because the occupation of most aliens is sedentary, whilst the occupations of the native are many and various. Two other features of the chart call for remark: (1) the incidence of phlyctenular conditions; and (2) the incidence of refraction cases.



Relative incidence of eye disease in alien and native patients.

1. Phlyctenular conditions or eruptions of the conjunctiva or cornea chiefly affect children and are due to nutritional defects more than any other cause. The incidence of this disease in alien and native differs less than any other inflammatory condition. The reason for this lesser liability of the alien to this form of inflammation as compared with other forms is to be sought in their diet. The staple food of the native poor children is tea with bread and butter. The staple food of the alien is richly impregnated with oil. Now the best cure for recurrent phlyctenulæ is cod-liver oil and plenty of it.

2. The incidence of refraction cases shows a marked excess of defective vision in aliens over natives: aliens 490, against natives 373. Now it is possible to check these figures, and in this check lies the test of the truth of the method I have used, comparison by reference to a constant. If the method be correct the figures I have found for the cases at the Royal London Ophthalmic Hospital should show a reasonable agreement with the incidence of defective sight in alien and native school children in London. I applied to Dr. J. Kerr, the medical officer of the late London School Board, for a return and he kindly furnished me with the following.

Comparative Conditions of Visual Acuity of Children attending the Senior Departments of Elementary Public Schools in London (December, 1903).

Group 1.	Group 2.	Group 3.
Jewish children, mostly natives of South Russia and of Poland, and living within a mile of Aldgate.	British children living under very similar conditions as to density of population, &c., as the children in Group 1.	Children of all varieties, local, social, and national conditions—i.e., average for London upon 30,000 children.
Defective 36 per cent.	*Defective 30 per cent.*	*Defective 26 per cent*

If my figures—aliens 490, natives 373—be both divided 14 they become, aliens 35, natives 26·7. The School Boar figures for similar groups of cases are 36 and 26 respectivel The test is a severe one, and the agreement in the finding obtained by two such diverse methods is the more strikin My figures differ only from those of the Board in bein lenient to the alien and severe to the native.

DIRT AND DISEASE.

A cause for the excess of disease is not far to seek; i lies in dirt and overcrowding. Last year I examined 21,89 children, of ages from seven to 14 years, in London Boar schools in the Hackney district. The schools were classed i three groups according as the scholars and their surrounding were of average or above or below average cleanliness. Th "clean" group of schools was in the north, where good housing and open spaces are found; the "dirty" group was dow towards the centre of London, in Hoxton and Bethnal Green. Amongst all schools, clean, average, and dirty, 351 cases of surface inflammations of the eye were noted—an incidence of 1·608 per cent. The incidence was more than twice as heavy in the "dirty" schools as in the "clean" schools, thus:—above average cleanliness, 0·873 per cent.; average cleanliness, 1·416 per cent.; below average cleanliness, 1·921 per cent. Further, a bacteriological examination of the flora of the conjunctiva was made in 100 healthy children (half of each sex, taken in fives in ages of five, seven, nine, 11, and 13 years), 50 in a school of superior cleanliness in North Hackney and 50 in a school below average cleanliness in the Bethnal Green district. The investigations were made last autumn during exceptionally wet weather, so that one common source of conjunctival contamination—dust—was absent. In the "dirty" group of children only three were found to have sterile conjunctivæ; in the other 47 cases 789 colonies were grown, making an average of 17 colonies per subject. In the "clean" group as many as 20 were found to have sterile conjunctivæ; in the remaining 30 cases 262 colonies were grown, an average of 9 per subject. Again, in one school of average cleanliness situated in the better part of Hoxton cultivations were made from the lid margins within the cilia. The head-master chose ten each of his cleanest and of his dirtiest children. All had eyes normal in appearance. All the cultivations were fertile. In the "dirty" group 680 colonies were obtained and in the "clean" group 610 colonies, showing a difference of 10 per cent. in favour of the clean children.

These bacteriological results show that dirt is not far removed from a synonym for disease, in that dirty and ill-kept children are the hosts of more septic organisms than clean children. The examination of native and alien patients shows that superficial inflammations of the eye are much more frequent in the alien than in the native; also that the alien is deficient in visual acuity to a much greater extent than the natives of London generally or of the very poor natives living under conditions similar to those of the poor alien.

The statement of Mr. Bryce that the aliens are "generally healthier than English workers" is not borne out by a reference to eye conditions.

Queen Anne-street, W.

EDUCATION IN "FIRST AID," ETC., FOR WOMEN IN RUSSIA.—According to a note in the *Novoe Vremya* of St. Petersburg the Society for the Promotion of the Professional Education of Women on May 7th opened a third six weeks' course of first aid to the wounded, treatment of the sick, and preparation of food for the sick. At the first and second series 180 women obtained certificates.

THE RELATION OF THE PANCREAS TO DIABETES AND THE QUESTION OF THE TRANSPLANTATION OF THAT GLAND AS A REMEDY FOR THE DISEASE.

BY JAMES W. ALLAN, M.B., C.M. GLASG.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY.

THE grave form of diabetes is not only hopeless but the patient is always liable to the sudden development of coma—and death. Therefore, it is not only justifiable but right that any method of treatment which holds out a reasonable hope of success should be tried if, after full explanation, the patient is willing to submit to it.

There is a great mass of evidence, physiological and pathological, pointing to disease of the pancreas (in some cases it may be only functional disorder of the pancreas) as one of the factors, probably the chief factor, in the production of diabetes. The physiology of the pancreas and its relation to diabetes have been carefully and laboriously investigated by a host of skilful and scientific observers, among whom may be mentioned Minkowsky, von Mering, De Dominis, Thiroloix, Hédon, and Lepine. It seems sad if out of all this mass of painstaking experiment and investigation we cannot obtain some therapeutic help for those cases of diabetes not amenable to dieting or to drug treatment and always more or less in danger of diabetic coma. In this connexion the following points may be considered. 1. It is well known that total extirpation of the pancreas induces diabetes. 2. If only a portion of the pancreas is left—even the splenic end—no diabetes occurs. 3. If pancreas is transplanted into an animal before its own pancreas is cut out no diabetes takes place. If the graft is removed diabetes occurs (Minkowsky, referred to by Williamson in Gibson's Medicine). 4. From 2 and 3 it is evident that the prevention of glycosuria is not due to the ordinary secretion of the pancreas, which flows into the duodenum by the duct of Wirsung. 5. It is reasonable to assume that the organ produces an internal sugar-destroying secretion (as contended by Lepine) and that the portion of gland left (2) or the transplanted gland (3) has the power of forming that sugar-destroying secretion or juice. 6. From the foregoing it might therefore be hoped that by transplantation of pancreas a case of diabetes might be cured or relieved. 7. Again, turning to the pathological aspect of the question, we find that disease of the pancreas is frequently associated with diabetes, as is shown post mortem. This is well known and it is, perhaps, unnecessary to cite particular instances. 8. But it must be admitted that there are many cases of diabetes in which no disease of the pancreas is detected. How are we to explain these cases? In the first place, a naked-eye examination may fail to reveal changes in the organ and it may be hastily pronounced "normal" or "healthy." But the real question is, Has the gland been subjected to a careful microscopic examination by a skilled observer and does that examination show the islands of Langerhans to be in a healthy condition? for in those islands the sugar-destroying ferment, the "internal secretion" of Lepine, is produced.

[illegible] a case of diabetes the [illegible] appearances, both macro[illegible] we to conclude that the disease cannot be due to the pancreas in any way? The reply is that there may be a defect in the innervation of the organ, its secretions may be checked by inhibitory nervous action—due to irritation or disease in the nerve centres, say in the floor of the fourth ventricle. I do not possess the profound or intimate knowledge of physiology to enable me to discuss this matter fully and if I did space would forbid. I shall therefore content myself with saying that it is well known that irritation at a certain spot on the floor of the fourth ventricle gives rise to glycosuria. (Osler mentions a curious case which he saw with Reis in Berlin where a woman who had "anomalous cerebral symptoms and diabetes" was found on post-mortem examination to have a cysticercus in the fourth ventricle.[1])

It is recognised that many cases of *diabetes mellitus* date, it may be immediately, from a mental shock or strong emotion. Is not this analogous to the jaundice which has been known to supervene on strong emotion of disgust. (A case in point has come under my observation.) In this instance it is to be presumed that the nervous influence disorders the function of the liver. In the case of diabetes due to shock may it not be a similar influence affecting the pancreas?

One other point. It may be urged that there are cases of disease of the pancreas with no diabetes. The question here is, Are the islands of Langerhans destroyed or not? If not the sugar-destroying function of the organ may remain.

It seems pretty clear, then, that the revelations of disease support the idea that there is a close association between the pancreas and diabetes. Pathologists tell us that hyperplasia of the intestinal mucous membrane is the most constant post-mortem appearance in diabetes. Granting this to be the case this hypertrophy is very probably *secondary* to pancreatic mischief, as it has been found to follow in cases of glycosuria induced by extirpation of the pancreas. This is important. Hédon says: "Chez les animaux qui ont survécu longtemps, on observe une ectasie parfois considérable de l'estomac et de l'intestin, avec hypertrophie de la tunique muqueuse (et développement anormal des glandes de Lieberkuhn d'après Martinotti et Boccardi)." Other pathological changes, also presumably *secondary*, are mentioned by Hédon[2]: "Le tissu du foie peut pré enter cependant un état de dégénérescence graisseuse plus ou moins avancé (v. Mering et Minkowski) ...... les reins sont aussi notablement hypertrophiés, ainsi que la vessie. Dans la moelle, Boccardi a rencontré une dégénérescence de la myéline et l'atrophie de certaines cellules nerveuse." These remarks come under the heading: "Extirpation totale du pancreas." Surely the pathological changes in liver, intestine, kidneys, and cord are very significant.

In myxœdema and cretinism benefit has been obtained by implanting thyroid gland. Only two instances need be cited here—Macpherson's[3] and Gibson's.[4] In the former the thyroid of a sheep was transplanted, a half under each mamma. The result was immediate improvement, due no doubt to "the absorption of secretion of the thyroid gland. But I have also reason to believe that a considerable portion of the gland I grafted became ultimately vascularised in the body of the patient." In the latter lamb's thyroid was employed in a child (myxœdematous sporadic cretin). The first grafting was under the sheath of the great pectoral just below the nipple, each lobe being laid open before insertion. In the second grafting one lobe was attached by a silkworm-gut stitch to the anterior left abdominal wall, the other being placed free in the right side of the abdominal cavity. I abstain from further details of these very interesting cases in order to economise space. I have selected these cases because the thyroid of an animal was employed, not human thyroid. Murray, Byrom Bramwell, Kocher, and Fenwick have done work in this field which is known to all the world. Complete extirpation of the thyroid induces myxœdema or cretinism; implantation of thyroid cures or relieves sufferers from myxœdema or cretinism. With these experiences before us, are we not justified in hoping that similar beneficial results may be got by the implantation of pancreas in diabetes? It is to be remembered that the production of the "internal secretion"—the sugar destroying ferment—is now referred to the islands of Langerhans and *these islands are in structure similar to the thyroid* inasmuch as they are closed ductless glands.

To sum up, physiological experiments, pathological experience, and the results of implanting thyroid in myxœdema all point to transplantation of pancreas in diabetes as a reasonable and justifiable proceeding. It may be urged against the proposal that the diabetic patient is a bad subject for surgical interference. I fear it must be admitted that he is not a desirable subject for operation. At the same time we must not overlook the fact that the myxœdematous patient is pretty much in the same category and that in his case transplantation of gland (although not unattended by some troublesome circumstances) has yielded happy results.

The labours of Murray and others have happily shown us that operation is not necessary for the relief of myxœdema.

---

[1] Osler's Medicine.

[2] Physiologie Normale et Pathologique du Pancréas, p. 151.

[3] Edinburgh Medical Journal, March, 1892.

[4] Brit. Med. Jour., Jan. 14th, 1893.

We know that the internal administration of the gland is attended with equally satisfactory results. But in the case of diabetes the internal administration of pancreas has given disappointment and therefore (in the meantime at least) we are compelled to turn our eyes to operative interference. Dr. P. Watson Williams of Clifton [5] has recorded an attempt to transplant pancreas in diabetes and another attempt was recently made in Glasgow Royal Infirmary.[6] Unfortunately, both of these were unsuccessful. Dr. Williams's case is very interesting and worthy of careful attention. One important fact in connexion with it I may note. The stools were not fatty, but on post-mortem examination the pancreas was found to be atrophied and wasted—a mass of connective tissue with little gland substance left.

This present communication does not aim at urging the operation. My object is to call the attention of my professional brethren to a very interesting and important question in practical therapeutics and to elicit the opinions of those who have more knowledge than myself.

It only remains to be said that if I had a case of diabetes under my care which refused to respond to dietetic or drug treatment and was drifting within range of diabetic coma I should be willing again to assume the responsibility of advising transplantation of pancreas on the following conditions: (1) that after full and honest explanation of *pros* and *cons* the patient requests that the operation shall be performed; (2) that the patient shall not be suffering from acetonuria at the time; and (3) that a sheep shall be killed close to, or in, the place of operation and its pancreas directly conveyed to the body of the patient.

Glasgow.

A CASE OF DERMOID CYST OF THE MESENTERY.

By J. BASIL HALL, M.C. CANTAB.,
HONORARY SURGEON TO THE ROYAL INFIRMARY, BRADFORD.

ALTHOUGH the existence of mesenteric cysts has been recognised for nearly four centuries it is only within the last 20 years that any systematic study of the subject has been made. In English surgical literature, however, very little except the records of isolated cases appeared until six years ago when Moynihan[1] published a valuable contribution in which he gave a comprehensive classification of the various forms of cyst that had been found in this situation. It was largely due to my knowledge of Moynihan's article and to my previous association with one of the cases which he recorded therein that I was able to recognise the condition prior to operation in the case which I now record.

The patient, a girl, aged eight years, was sent to me by Dr. H. Munro of Bradford on March 20th, 1903. Her mother stated that she had first noticed a lump in the child's abdomen four months prior to my seeing her. About three weeks later the patient had diphtheria and went into the fever hospital. The attack was followed by some diphtheritic paralysis. Since returning home the abdominal tumour had increased very considerably in size but had given rise to no symptoms. The patient's condition on examination was as follows. She was a well-grown girl of rather fragile appearance and somewhat thin. There were a distinct nasal intonation and some slight paralysis of the palate still remaining. The knee-jerks were absent and the pulse was quick, varying from 100 to 120 per minute. In other respects the general health appeared to be good. On uncovering the abdomen a prominent tumour was seen on the right of the middle line at the level of the umbilicus. It felt to be of about the size of an English melon and was smooth and globular. In consistence it was highly elastic. It was dull on percussion and there was no tenderness. When the patient lay on her back it sank most readily into the right lumbar region. It could easily be displaced, however, to the left of the middle line and also downwards towards the pelvis, and when displaced it remained in its new position. It was quite free from any liver attachment and the colon did not lie in front of it. Its extreme mobility also negatived the possibility of renal origin. No connexion with the pelvic organs could be demonstrated and, moreover, of all its movements that in a downward direction was the most limited. The urine was normal as were also the intestinal functions. There was no history of any subjective symptoms obtainable. The diagnosis of mesenteric cyst was made, but in view of the post-diphtheritic palsy it was decided to wait for a short period before operating. The patient was kept in bed for three weeks under medical treatment during which time her general condition much improved. The tumour did not perceptibly increase in size during this period.

Operation.—On April 16th ether was administered and the abdomen was opened through the sheath of the right rectus muscle. A cystic tumour was found lying in the mesentery of the ileum. The cyst wall was thick and pearly-white in colour and very scantily supplied with blood vessels. At this stage the pulse became alarmingly rapid and it was evident that the patient would not endure any prolonged operation. The edges of the incision were therefore attached to the cyst with a few sutures and the wound was packed with gauze. For the next two days the child was very ill, with a very rapid pulse and symptoms of shock. She then improved and soon seemed none the worse. This alarming collapse could only be attributed to the post-diphtheritic state and it was decided simply to incise the cyst and to drain it as soon as adhesions had formed. On April 23rd, therefore, ether was again given and the dressings were removed. It was then found that no adhesions had formed between the cyst and the abdominal wall and as the patient bore the anæsthetic well it was decided to attempt removal. The abdominal cavity was packed off with gauze and the cyst was incised. A pint of thick creamy fluid escaped. The cyst wall was easily peeled from the mesentery with the exception of a couple of square inches which were closely incorporated and could not be removed without endangering the blood-supply of the gut. The whole cyst wall, therefore, was cut away excepting this small area which was fixed to the edges of the peritoneum in the lower parts of the wound. This portion of the incision was left open and packed with gauze whilst the upper half was closed with sutures. The patient bore the operation well. The portion of the wound which was packed healed by granulation in eight weeks and left a firm scar. The child has continued in excellent health since the operation.

The disposition of the tumour and the viscera when the abdomen was opened was as follows. The cyst, which was as large as a cocoanut, lay in the mesentery of the ileum. It occupied the whole breadth of it except for an inch on either side at the fixed and free borders. The narrow strip of mesentery between the gut and the cyst was abnormally thick and fleshy. So far as it was possible to estimate by a rapid survey its site was about 25 inches above the ileocæcal valve. There was no ascending colon; the cæcum and appendix were lying in the epigastrium above and to the left of the tumour. The ileum therefore almost completely encircled the cyst, passing first along its lower border, then up the right side, and finally above it from left to right to reach the cæcum in the epigastrium. In front of the cyst the anterior or upper layer of the mesentery had practically disappeared from atrophy so that only the posterior aspect of the tumour had any mesenteric attachment. The cyst contained a pint of thick creamy material of treacly consistence. There were a very few fine hairs in it and some pasty masses which appeared to be conglomerations of flattened epithelium. There were large quantities of oil globules which blackened when treated with osmic acid. The interior of the cyst wall was granular and roughened as if inflammatory changes had occurred in it. There were also considerable patches of ecchymosis in the wall. Sections under the microscope failed to demonstrate any epithelial lining, the latter having apparently been entirely destroyed. There seems no doubt, therefore, that the tumour was a dermoid cyst of the mesentery in which degenerative changes had occurred.

The case appears to me to possess an interest over and above those hitherto recorded from the fact that the conditions found at the operation seem to have some bearing on the etiology of the growth. The situation of the cyst was that in which the remains of the vitelline duct are not uncommonly found and the large intestine was imperfectly developed. The cæcum occupied the position which is attained about the third month of fœtal life. Whilst the first may be purely a coincidence the two circumstances in association lend colour to the view that the cyst owed its origin to a defect in the alimentary canal and that such defect occurred about the third month of fœtal existence. The condition of the ovaries could not be definitely ascertained at the operation without enlarging the incision, a procedure which was not deemed justifiable. The right ovary could just be reached with the finger tips and appeared to be normal.

[6] Ibid., Feb. 28th and March 21st and 28th, 1903.

[1] Annals of Surgery, July, 1897.

Of the clinical features the most striking were the extreme mobility of the tumour, its marked globular shape, and its central position. Excepting when it rolled back into the loin the most prominent point of the tumour lay immediately on the right of the umbilicus.

The only complication in the treatment was the alarming collapse on the first occasion of opening the abdomen. The child had not been under ether more than five minutes, just long enough, in fact, to open the abdomen and to ascertain the site and attachments of the tumour. On the second occasion the cyst was incised and emptied *in situ* and then drawn out of the abdomen. It is possible, therefore, that on the first occasion the handling of the large tense cyst may have caused some pressure on the solar plexus and so produced the collapse.

Bradford.

NEURO-RETINITIS IN CHLOROSIS.[1]

BY J. JAMESON EVANS, M.D. BIRM., F.R.C.S. ENG.,
HONORARY SURGEON TO THE BIRMINGHAM AND MIDLAND
EYE HOSPITAL.

Hirschberg in 1879 was the first to note the occurrence *of optic neuritis due to chlorosis. Since then cases have* been recorded by Gowers, Herschel, Richard Williams, and others. In 1882 Saundby and Eales investigated the state of the fundus oculi in 50 cases of chlorosis. They found some abnormal appearance of the fundus in 32 per cent. of the cases and some degree of neuro-retinitis in 8 per cent. This striking result would have convinced most people of the comparative frequency of retinal changes in chlorosis, and yet such a reliable ophthalmoscopist as Max Knies says "hæmorrhages into the fundus never occur in chlorosis" and "in view of the rarity of these cases (neuritis and neuro-retinitis) and the frequency of chlorosis this association may be a mere coincidence." I question if many ophthalmologists will be found to agree with these statements. So far as I am concerned I am fully convinced that the condition is far from being rare and clearly stands to chlorosis in the relation of effect and cause.

The pathological changes which have been observed in the fundus in cases of chlorosis include arterial pulsation, pallor of the fundus, disc and vessels, broadening of the veins, and dulling of the light streak. The arteries may be comparatively and absolutely narrower than normal, though their light streak is broader than usual. These changes are of little or no diagnostic or prognostic significance. Of much more serious import are optic neuritis, neuro-retinitis, and retinal hæmorrhages. The neuritis naturally varies in degree but it is often intense and of the "choked-disc" type. The neuritis may or may [illegible] retinal hæmorrhages. [illegible] though some cases sh[illegible] White degenerative patches are often present and may form star- or fan-shaped figures in the *macular region. The* appearances generally simulate those seen in intracranial disease but they may be very suggestive of albuminuric retinitis in some cases. It is well in all cases of this sort to examine the urine and carefully to consider the possibility of intracranial mischief, notably syphilitic new growths. Hæmorrhages more or less extensive may occur without neuritis.

Max Knies has described degenerative changes around the yellow spot simulating those of albuminuria but without any neuritis or retinitis and with little or no impairment of vision. They were always unilateral and disappeared completely in about six months. The degree to which vision is affected by these changes is very variable. In some of the more acute cases vision is only slightly below normal during the early stages. This is unfortunate, as much valuable time may be lost owing to lack of symptoms suggestive of profound pathological fundus changes. In the later stages, when atrophy of the optic nerve has set in, the sight is seriously and permanently impaired. Large hæmorrhages in the macular region are followed by marked impairment of vision owing to destruction of the retinal elements by the extravasation. If diagnosed early and vigorously treated much improvement of vision and even recovery of normal vision may be looked for (*vide* cases).

The fields of vision are generally slightly contracted owing to atrophy of some of the nerve fibres. The atrophy is not progressive and the amount of contraction is governed by the extent to which the nerve fibres have been destroyed during the inflammatory period. The contraction is generally more or less concentric. Extensive patches of retinitis or hæmorrhage may give rise to scotomata, but these are seldom complained of by the patient.

The condition of the blood in cases of chlorosis presenting retinal changes requires further investigation. The records so far are not complete enough. Gowers is inclined to think that in the cases which show marked optic neuritis the hæmoglobin is reduced out of all proportion to the corpuscles and that hæmorrhages only take place where there is an absolute deficiency in the number of red corpuscles. This assumption is scarcely warranted on the strength of the limited number of cases published, but it seems supported by the fact that in pernicious anæmia (corpuscular defect) hæmorrhages are much more common than neuritis. Stephen Mackenzie, from observations made on a good number of cases, has come to the conclusion that a reduction of 50 per cent. in the number of corpuscles indicates a tendency to retinal hæmorrhages. He makes no reference to the state of the blood in cases of simple neuritis without hæmorrhages. I have not been impressed by any distinct relationship between the blood condition and the character of the retinal changes. Some slight irregularity of shape of the red corpuscles and imperfect rouleau formation have been observed. The leucocytes did not show any abnormality and their number varied from 4000 to 8000 per cubic millimetre in my cases.

It is of great importance that the neuro-retinitis of chlorosis should be diagnosed early, otherwise atrophy of the nerve will inevitably develop and the sight will be permanently damaged. To avoid such a calamity all cases of profound or even marked anæmia should be examined ophthalmoscopically and the treatment should be conducted with due reference to the state of the retina and optic nerve. It is important not to mistake the neuro-retinitis of anæmia for that due to syphilis or intracranial growths as it involves the possibility of harmful treatment (with iodide of potassium, &c.) as well as destructive delay. A rapidly developed neuro-retinitis, especially if it assumes an acute form, occurring in a patient whose hæmoglobin or red blood corpuscles are reduced to 50 per cent. or less and who shows no signs of a cerebral lesion may with a considerable degree of certainty be put down as anæmic in origin.

No satisfactory theory as to the cause of the neuritis and hæmorrhages occurring in chlorosis has been propounded. Gowers holds that the hypermetropia which is frequently present in these cases causes a (natural) slight congestion of the nerve, which in the anæmic state of the blood becomes intensified into a neuritis. Hawthorne has suggested that thrombosis of the cavernous sinus is the primary cause of the neuro-retinitis. I am inclined to think that degenerative change, probably fatty, in the vessel wall associated with the change in the composition and intravascular pressure of the blood are the most *likely factors in its production.* A discrepancy between the intravascular and intra ocular pressures might easily lead to serous effusion and rupture of blood vessels weakened by disease.

The prognosis with regard to recovery of sight is good if the case be diagnosed early and treated energetically. This [illegible] pronounced neuritis of the [illegible] which fully recover their [illegible] no contraction of the visual fields. If for any reason the inflammatory changes are allowed to take their own course—e.g., through incomplete or mistaken diagnosis or carelessness on the part of the [illegible] atrophy of the optic nerve [illegible]ion and contracted visual [illegible]morrhages if extensive and [illegible] by a much diminished visual acuity, but even here the prognosis is not so unfavourable as might be expected, judging by the ophthalmoscopic appearances during the early stages.

---

[1] Extracted from a paper read before the Midland Medical Society in March, 1903.

The treatment is the ordinary routine for chlorosis—viz., iron, with or without arsenic. Due attention should be given to disturbances of the intestinal tract. The iron should be pushed to the utmost as it is essential that the action should be prompt so as to avoid the extension of the inflammatory changes and the development of optic atrophy. The eyes should be shaded either with smoked glasses or a bandage. It is not necessary or even advisable to darken the room. The patient should be kept in bed. Absolute rest of body and eyes is essential in these cases as the neuro-retinitis indicates a degeneration of the vascular system.

The following cases are illustrative of the more pronounced fundus changes seen in chlorosis. The blood examinations are not as complete as one could wish, but they are sufficiently so to indicate the degrees of anæmia which may give rise to ocular lesions. They also give a good idea of the course and progress of such cases and the ultimate results of treatment.

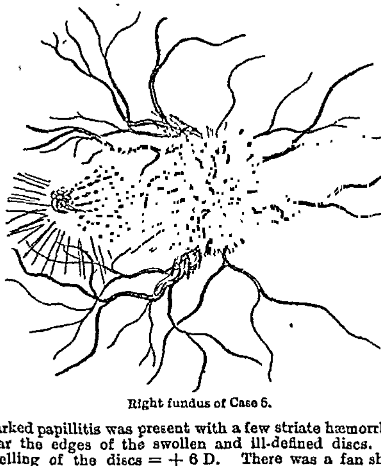
CASE 1.—The patient was a girl, aged 17 years, who was admitted to hospital on Dec. 15th, 1898. She had been suffering from frontal headaches for a month. She had vomited three times during the month. Menstruation was regular. She had not noticed anything wrong with her sight. On ophthalmoscopic examination it was found that she had optic neuritis in each eye. The discs were very swollen, enlarged, and "woolly," and showed some glistening deposits. There were no hæmorrhages. The vision was R.V. = $\frac{6}{12}$ c. + 5 D.; L.V. = $\frac{6}{9}$ c. $\frac{+ 5 \text{ D. sph.}}{+ 2{\cdot}5 \text{ D. cyl. } \phi_{90}}$. The fields were contracted slightly (about 10°) on the temporal side. Blood examination gave the following result: hæmoglobin, 35 per cent.; red corpuscles, 3,640,000 per cubic millimetre; and white corpuscles, 7500 per cubic millimetre. The colour index was 0·43. The heart and urine were normal. The treatment consisted of pil. Blaud iii. three times a day and a mixture containing iron and arsenic as well. Cascara sagrada in tabloid form was given every night. On Dec. 20th a blood examination gave the following result: hæmoglobin, 45 per cent.; red corpuscles, 3,780,000 per cubic millimetre; and white corpuscles, 7500 per cubic millimetre. Treatment was as above and burgundy, raw beef, and sandwiches were included in the diet. On the 31st the swelling of the discs was less marked. R.V. = $\frac{6}{9}$ c. + 4 50 D. sph.; L.V. = $\frac{6}{9}$ c. $\frac{+ 4{\cdot}5 \text{ D. sph.}}{+ 2{\cdot}5 \text{ D. cyl. } \phi_{90}}$. The following is the result of the blood examination: hæmoglobin, 58 per cent.; red corpuscles, 3,980,000 per cubic millimetre; and white corpuscles, 7000 per cubic millimetre. On Jan. 5th, 1899, there was still marked swelling of the discs—viz., the right summit was seen best with + 8 D. and the left ditto with + 7 D. The vision was the same as on Dec. 31st. On Jan. 10th the blood was again examined with the following result: hæmoglobin, 70 per cent.; red blood corpuscles, 4,240,000 per cubic millimetre; and white blood corpuscles, 6500 per cubic millimetre. The patient was discharged on this day.

CASE 2.—The patient was a girl, aged 18 years, who was admitted to hospital on April 11th, 1899. Her sight had been failing slightly since January of the same year. A month before admission it became so bad that she had to give up her work and was treated for anæmia by her own medical adviser. During the two weeks preceding the date of admission her sight had still further deteriorated; she had also suffered from frontal headaches and she had vomited two or three times. There was no evidence of her having had hæmatemesis. On admission the pupils were widely dilated and did not react to light. The optic discs were swollen (+ 4 D.) and pale and showed numerous fine hæmorrhages. The veins were tortuous and obscured in places near the discs by exudation. The maculæ had a faint striated appearance. R.V. = perception of hand movements; projection was good. L.V. = no perception of light. The following is the result of the examination of the blood: hæmoglobin, 60 per cent.; red blood corpuscles, 3,960,000 per cubic millimetre; and white blood corpuscles, 6250 per cubic millimetre. The colour index was 0 68. There was a trace of albumin in the urine; the specific gravity of the latter was 1015. All other systems were normal. Treatment consisted of Blaud pill with arsenic and nux vomica and potassium iodide in mixture and some mistura alba every morning. The diet included fish, beef-tea, raw meat, and claret. On April 18th no headache was present. The right pupil reacted slightly to light. R.V. = perception of hand movements; L.V. = no perception of light. On the 23rd blood examination gave the following result: hæmoglobin, 70 per cent.; red blood corpuscles, 4,320 000 per cubic millimetre; and white blood corpuscles, 6250 per cubic millimetre. On May 1st the swelling of the discs was less (+ 2·5 D.). The pallor of the discs was more pronounced. There were a few small hæmorrhages still on the discs. The veins were of about normal size but the arteries were contracted. On the 8th the blood was again examined with the following result: hæmoglobin, 76 per cent.; red blood corpuscles, 4,600,000 per cubic millimetre; and white blood corpuscles, 8750 per cubic millimetre. There were no further change in the appearance of the fundus and no improvement of vision and the patient was discharged on May 19th. It is evident from the history that this patient had been suffering from optic neuritis for three or four months before admission. There was evident atrophy of the nerve on admission and this became more marked during her stay in hospital. No further improvement was to be expected and she was consequently discharged. The favourable condition of the blood was no doubt due to the treatment received before admission.

CASE 3.—The patient was a girl, aged 17 years, who was admitted to hospital on Jan. 14th, 1899. Her present illness began about five weeks before admission with frontal headaches, giddiness, and sickness, and some vomiting after food. There was no indication of hæmatemesis. Sight had been failing for two weeks before admission. Amenorrhœa had persisted for two months. On admission the patient showed marked pallor of her mucous membranes. The pupils were dilated (ten millimetres) though they reacted well to light and accommodation. The media were clear. The optic discs were much swollen (+ 4 D.) and their centres were filled in with whitish exudation. The veins were distended and tortuous. There were numerous fine striate and punctiform hæmorrhages in the region of the discs and maculæ. White degenerative spots were also to be seen in the yellow spot region in each eye. R.V. = $\frac{6}{36}$ c. + 2 D.; L.V. = counting fingers at two feet. The colour vision was impaired. On examination of the blood the following result was obtained: hæmoglobin, 38 per cent.; red blood corpuscles, 2,840,000 per cubic millimetre; and white blood corpuscles, 10,000 per cubic millimetre. The colour index was 0·60. The other systems were normal except for a systolic murmur heard over the apex and the base of the heart and conducted into the axilla. The treatment was the same as that in Case 1. On Jan. 19th a blood examination was made with the following result: hæmoglobin, 48 per cent.; red blood corpuscles, 3,420,000 per cubic millimetre; and white blood corpuscles, 9500 per cubic millimetre. R.V. = $\frac{6}{18}$ c. + 1·5 D.; L.V. = counting fingers at four feet. On the 30th the discs were slightly less swollen and paler. R.V. = $\frac{6}{18}$ c. + 2 D.; L.V. = $\frac{6}{24}$ c. + 2 D. A blood examination gave the following result: hæmoglobin, 58 per cent.; red blood corpuscles, 3,800,000 per cubic millimetre; and white blood corpuscles, 8750 per cubic millimetre. On Feb. 6th R.V. = $\frac{6}{18}$ c. + 2 D.; L.V. = $\frac{6}{36}$ c. + 2 D. The discs were paler. On the 13th the blood was examined with the following result: hæmoglobin, 70 per cent.; red blood corpuscles, 4,660,000 per cubic millimetre; and white blood corpuscles, 7812 per cubic millimetre. On the 26th the result of the blood examination was: hæmoglobin, 76 per cent.; red blood corpuscles, 4,500,000 per cubic millimetre; and white blood corpuscles, 6875 per cubic millimetre. R.V. = $\frac{6}{18}$; L.V. = $\frac{6}{36}$. The discs were very pale, with indistinct edges; the blood-vessels (especially the arteries) were contracted. There was slight swelling of the discs. On March 12th the blood was examined with the following result: hæmoglobin, 75 per cent.; red blood corpuscles, 4,360,000 per cubic millimetre; and white blood corpuscles, 5000 per cubic millimetre. The vision was the same as on Feb. 28th. The patient was discharged on March 13th.

CASE 4.—The patient was a female, aged 24 years, who was admitted to hospital on June 20th, 1899. Six weeks before admission she had had a severe attack of hæmatemesis. This had no noticeable effect on her sight but a less severe attack just before admission made her feel so "giddy and dazzled" that she had to be led to bed. On admission she was pale and waxen in appearance. The conjunctivæ were markedly pale and there was a slight whitish, sticky discharge which glued the *lids* together a little in the mornings. The corneæ lacked brilliancy. The media were clear; the right pupil was active and the left l divergent strabismus. the edges were blurred cured the vessels. The veins were full and tortuous; the arteries were smaller than normal and difficult to see. The retina in the region of the disc and yellow spot was œdematous. A few small striate hæmorrhages were visible along the course of the vessels near the disc. In the macular region were about four well-marked soft grey patches showing hæmorrhagic borders. In between the patches were a few small punctate hæmorrhages. The left optic disc was not so swollen and the edges were better defined. There was less œdema of the retina and the veins were less full and tortuous, while the arteries were more visible and larger. The hæmorrhages were fewer and the grey patches at the macula were fewer (two). Blood examination gave the following result: hæmoglobin, 10 per cent.; red blood corpuscles, 1,012,500 per cubic millimetre; and white blood corpuscles, 8200 per cubic millimetre. The colour index was 0·44. The blood was examined on July 5th, the result being as follows: hæmoglobin, 10 per cent.; and red blood corpuscles, 1,392,000 per cubic millimetre. Stained films showed great variety in the size of the red cells, some very large, some very small, some evidently degenerating, many poikilocytes, a very few nucleated red cells, some normoblasts (one with a nucleus showing mitosis), and one or two megaloblasts. There was an apparent increase in blood plates. There was no apparent increase in the leucocytes. Some increase in transitional forms was noted as well as some atypical myelocytes. On August 4th the blood was again examined with the following result: hæmoglobin, 54 per cent.; red blood corpuscles, 3,000,000 per cubic millimetre; and white blood corpuscles, 7080 per cubic millimetre. Stained films showed a few poikilocytes and microcytes but no nucleated red cells. The red cells were of fairly uniform size and stained evenly. No abnormal leucocytes were observed. The patient was discharged on August 6th. She unfortunately left the hospital without having her vision tested but the deterioration was evidently not such as to cause her any inconvenience.

CASE 5.—The patient, a girl, aged 19 years, was admitted to hospital on Jan. 4th, 1899. The general health had been indifferent for two months. The sight had been failing for a month; several times a day it would get "misty" for a second or two and then clear up again. On admission the mucous membranes and skin were very pale. The patient had suffered from breathlessness and constipation. There was a basal murmur. The pupils were normal.



Right fundus of Case 5.

Marked papillitis was present with a few striate hæmorrhages near the edges of the swollen and ill-defined discs. The swelling of the discs = + 6 D. There was a fan shaped arrangement of white degenerative lines and spots extending between the yellow spots and discs. The foveæ were occupied by a dark brown network situated superficially to the white lines. R.V. = $\frac{6}{12}$ c. + 4 5 D.; L.V. = $\frac{6}{12}$ c. + 5 D. The treatment was the same as that carried out in Case 1. On Jan. 10th the blood was examined, the result being as follows: hæmoglobin, 50 per cent.; and red blood corpuscles, 3,400,000 per cubic millimetre. The colour index was 0·7. On the 31st R.V. = $\frac{6}{9}$ c. $\frac{+4\cdot5}{+0\cdot50\ \phi_{30}}$; L.V. = $\frac{6}{12}$ c. + 6·5 D. The fundi were *in statu quo* (*vide* illustration). On Feb. 16th R.V. = $\frac{6}{9}$ c. $\frac{+5\text{ D.}}{+0\ 50\ \phi_{90}}$; L.V. = $\frac{6}{9}$ c. + 6 D. There were much less swelling of the discs and very little effusion into the retinæ. The degenerative changes near the yellow spot were *in statu quo*. The patient was discharged on May 4th.

Birmingham.

FASTING IN THERAPEUTICS.

By JOHN HADDON, M.A., M.D. EDIN.

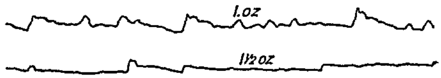
HAVING had occasion to study diet my attention has been directed to fasting as a therapeutic agent and the following case seems worthy of record.

The patient was a man, aged 65 years, who had been a hard drinker and a good eater all his life, working on contracts. He was much crushed and nearly drowned by scaffolding falling upon him. His life was for some time despaired of but he recovered. When I saw him seven years after the accident he weighed 18 stones, was crippled on one foot, and walked with a stick very slowly. He could not sleep in the night from coughing and spitting, passed urine every hour, and could hardly turn in bed from a stabbing pain in the side. He could not dress himself and was altogether in a pitiable condition. Having seen him I promised him that if he would follow my advice he would renew his youth. He was a man of powerful will and he said that he would do anything to get well.

I put him upon a little fruit twice daily. In five days he lost ten pounds in weight and he could dress himself and lace his boots which he had not done for years. As he lost weight his vigour increased and he began to work in his garden and to take long walks. All his troublesome symptoms left him and he could sleep like a child from 9 P.M. to 4 A.M. without waking. He had to get new clothes to suit his reduced size and in November (he began in June to restrict his diet) declared that he felt as well as ever he did and were it not for the damage he had received in the accident he might resume work as before. On Nov. 10th I saw him wheeling up a hill a barrowful of potatoes which he had himself dug out in the field.

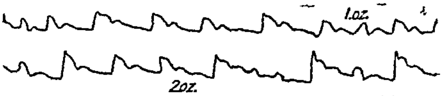
The change in his pulse was remarkable (Figs. 1 and 2). I never felt or saw a pulse so irregular and intermittent in character at first but it gradually improved and became fairly regular which the sphygmographic tracings show very clearly.

FIG. 1.



Pulse tracing, June 16th, 1903. Pressure one ounce and one and a-half ounces.

FIG. 2.



Pulse tracing, Oct. 18th, 1903. Pressure one ounce and two ounces.

He said he was neither hungry nor thirsty on the fruit diet. He now eats only about a quarter of what he did formerly and when the weather prevents him working or walking he at once gains weight.

This case seems deserving of attention from the marvellous change produced by abstinence and may encourage us to try a partial or perfect fast in suitable cases.

Denholm, N.B.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TAPEWORM AS A CAUSE OF CHOREA.

BY H. TENER GALBRAITH, F.R.C.S. EDIN.,
DISTRICT HEALTH OFFICER, DUNDEE, NATAL.

UNDER the heading of "Clinical Notes" some remarks were published in THE LANCET of Sept. 19th, 1903, p. 824, on the relation of tapeworm as a causative factor in chorea. The following case of the same kind is of interest.

A boy, aged ten years, said to be suffering from tapeworm, was brought to me by his father on August 6th, 1903. Male fern had been administered some time previously and had caused a partial expulsion of the worm, but the effect of the drug was so drastic that a repetition of the treatment was not considered desirable. The patient had just returned from the coast where he had been taken a month previously when convalescent from measles. He looked thin and pale and had derived no benefit from the change, indeed, according to his father's statement, he was actually worse and had recently appeared tired and breathless after slight exertion. Examination of the chest disclosed a well-marked mitral murmur the existence of which was unknown to the father. I prescribed syrup of iodide of iron and phosphate of iron; kousso was also given for the purpose of expelling the worm. On August 22nd the boy was again brought to me and this time for chorea which had developed in the interval since his last visit. The movements were bilateral and especially marked on the right side. The kousso had been unsuccessful and had been vomited. The coincidence of the presence of the worm and the onset of the chorea led me to the conclusion that possibly the irritation of the former had a distinct influence on the nervous system and more particularly in the patient's weak and anæmic condition. Bromides and arsenic were ordered and fluid extract of pomegranate bark was selected to deal with the parasite. Again only some segments of the worm were passed, so I decided to wait for a month before making a fresh attempt. On Sept. 10th the extract of pomegranate bark was again administered and this time the dose was increased to eight fluid drachms but without material success. No improvement had taken place in the chorea or general condition. By mutual agreement with the patient's father it was decided that the worm must be brought away, so operations were commenced by ordering that the boy should be fed extensively with onions. After a week of this treatment 12 drachms of fluid extract of pomegranate bark were given and some hours afterwards several feet of worm were brought to me by the boy's father. Next morning the dose was repeated and the same afternoon the remainder of the worm, including the head, was produced for my inspection. After this the chorea rapidly diminished and in another month was barely perceptible Due precautions as to starvation and the administration of purgatives were observed each time that a vermifuge was administered.

The chief point of interest in this case centres in the coincidence of chorea supervening in the presence of the intestinal parasite and the prior recognition of the heart murmur which may be fairly ascribed to the attack of measles from which the patient had suffered some time previously. Although endocarditis is uncommon in simple epidemic measles there can be little doubt that it occurred in this instance without being recognised by the medical attendant. No history of rheumatism or of any disease other than the recent attack of measles could be elicited to account for the heart murmur.

The relation of intestinal parasites as an exciting cause in the etiology of chorea in not mentioned by any of the authorities whose works are available to me for reference, not even in Dr. L. Starr's extensive treatise on the diseases of children—a book in which such reference might be expected. It is not suggested that the presence of intestinal parasites acts in any other manner than by maintaining a continued peripheral irritation of the intestinal mucosa which acts on the motor centres and sooner or later produces functional excitement. The presence of anæmia, malnutrition, febrile disease, or any weakening influence would be predisposing causes in such circumstances. While the etiology of chorea is still an unsettled point the preponderance of opinion seems to point to a neurosis or peripheral irritation as the cause, while the endocardial lesions are explained as due to a secondary infection. Dr. Starr in an analysis of 1400 cases finds that heredity and infectious disease bear no definite relation in the etiology of chorea, the most constant element being malnutrition. Gerhardt comes to similar conclusions, most other statistics show that a *considerable proportion of cases belong to families of a* neurotic type, and all sources agree on the great preponderance of incidence in the female sex. This preponderance of chorea in females may be regarded as in favour of a neurotic origin of the disease and the more so when their predisposition to anæmia and various neuroses must be admitted. Anæmia appears to be present in more or less degree in all cases and probably precedes the chorea. The occurrence of chorea in pregnancy is difficult to explain otherwise than from emotional causes or peripheral irritation through foetal movements. During the Anglo-Boer war three such cases occurred in my practice in Boer women whose husbands were on commando and all at the one period—namely, after the relief of Ladysmith, when the Boer forces were in a panic and *sauve qui peut* was the predominant idea. In these three cases, though the cause was due to fright and the hysterical form of chorea to be expected with more or less rhythmical movements, the movements were distinctly spasmodic, irregular, and increased by voluntary efforts.

During 1903 four cases of chorea occurred in my practice, including the one I have detailed. The remaining three were females, aged seven, ten, and 15 years respectively; in none was there any history of rheumatism and all were anæmic. In the female cases one only could be associated with an apparent cause—namely, a secondary amenorrhœa in the girl aged 15 years. Treatment directed entirely to this was followed by a disappearance of the chorea in the month following the return of the menses. There was a distinct increase of chorea in this district during the year 1903 and as a coincidence an epidemic of acute anterior poliomyelitis of a mild type, six cases arising in my own practice. So remarkably prevalent was this epidemic that I had an inquiry from the health officer of the Colony on the subject, as the outbreak had been brought to his notice from other districts in the Colony.

Dundee, Natal.

A CASE OF TAPEWORM IN A CHILD.

BY J. A. RIGBY, M.D. LOND.

THE patient was a pale, delicate-looking girl, aged two years and ten months, and was brought to see me with the following symptoms and history. She had a variable appetite and was uncertain and irritable in her temper, was restless at night, and did not thrive as she ought to do. Her mother informed me that she was in the habit of eating raw meat and she had been encouraged to do this under the impression that it would tend to increase her strength. I suggested that she might be suffering from tapeworm and directed the mother to inspect carefully the stools so as to discover if she were. On my next visit the mother showed me a motion which contained distinct evidence that the child was suffering from tapeworm, as there were several links of two or three proglottides each in it. A careful watch was kept up and it was found that she was constantly passing segments of the worm.

Tapeworm in young children is not unknown but it is comparatively very rare. In the course of a fairly extensive practice extending over 30 years this is only the second case I have met with. The treatment of tapeworm in adults presents no difficulty but in the case of children it is somewhat different, as the dose of the remedy sufficient to kill the worm might possibly have a very deleterious effect on the child. On looking up the subject I found that most authorities when describing the treatment of cases suffering from tapeworm make no discrimination as to the treatment of cases occurring in children. It would, I think, be conceded that to administer a dose of from 30 to 120 minims of the liquid extract of male fern on an empty stomach to a child under three years of age would scarcely be an advisable proceeding. Dr. I. Burney Yeo says:[1] "Pumpkin seeds have been found a mild and useful tæniacide for children and not unpleasant to take ...... About one ounce of the seeds may be given a child for a dose and they may be pounded up with sugar and honey into a paste which children will readily eat." This remedy was prepared as directed and given to the child on two separate occasions at about a fortnight's interval with absolutely no results whatever, the segments being constantly thrown off in the stools exactly the same as before.

The reason for this paper being written is because of the simple and efficacious treatment that was then adopted and which, while proving quite effective, had no injurious effect on the child. Two teaspoonfuls of castor oil were administered at night and the following morning this mixture was given. A drachm of kousso was infused for 30 minutes in three ounces of boiling water. To this three drachms of the liquid extract of liquorice were added. One-third part of this mixture, which was not strained but was well shaken up, was administered every two hours. The child took it without any difficulty and the result was most satisfactory, as in a few hours a worm of great length was expelled, and although the head was not found the segments became so very fine that it was quite certain the head must have been detached at the same time, though not discovered. There have been no signs of any return since, although now three months have elapsed.

Preston.

NOTE ON THE ACTION OF CROTON OIL AND OF PILOCARPINE

By William Roper, L.R.C.P., L.R.C S. Edin.

A brief *résumé* of some of the effects observed during a frequent use of croton oil in minute doses will probably present some features of interest. In the first case which I will select as an illustration the patient was a black man in South Africa who some years ago, after a heavy meal, had a great lump or bolus in his stomach. He was purged by calomel without relief. No vomiting of the bolus or any improvement was obtained with zinc sulphate and with apomorphine given hypodermically. Two minims of croton oil were then given, a small dose for a black man who is tolerant of more than four times the purging necessary for a white man. The effect of this was vomiting without purging and with reduction of the bolus, the effect of four minims subsequently given being both vomiting and purging. The man made a good recovery.

In the following cases all the patients were white men. My first cases of seasickness and of diarrhœa treated with

kness made a good recovery as a result of taking castor oil containing one-fifth of a minim of croton oil to the teaspoonful.

Another man had diarrhœa for two or three days with five evacuations in the last two and a half hours I gave him half a teaspoonful of crotonised castor oil containing one-tenth of a minim of croton oil. He repeated the dose in an hour and four hours later he reported that there had been no further evacuations but that he experienced a sensation of something bearing down lower and lower in his bowels. Four hours later he reported one evacuation and then a normal condition prevailed. This slow action of croton oil seemed to show that there was a morbid irritant needing expulsion.

A man under my treatment once took in a fortnight about 50 full doses of calomel followed by Epsom salts and then after this he reported that he felt under croton oil a sensation of "scraping" and that he passed black fæces—a colour unlike that of the fæces previously passed. A strange contrast exists between the action of full and minute doses of croton oil. In both a sensation of movement quickly follows administration, the interval between a sensation of movement and evacuations being in full doses sometimes only a few minutes and in minute doses sometimes a whole day and frequently half a day. Many after taking suitable doses of croton oil think its action most pleasant, increasing the appetite, a point worth noting, also supporting the opinion that it only causes pain when something such as an impacted mass requires to be moved. In these cases when a first dose is painful a second is frequently pleasant and stimulating.

The addition of croton oil to a bottleful of castor oil facilitates accurate dosage of the former and economises the latter. The above instances seem to show that croton oil when given in suitable doses cleans the whole intestinal canal without causing so much irritation as some other purgatives. This cleansing of the bowels of what may be left behind by other agents—purgatives and emetics—seems to indicate an extended field for the employment of a drug little used by the profession except as a last resort in obstinate constipation.

While writing on this subject I may be permitted to refer to my inquiry published in The Lancet of August 1st, 1903, p. 342, regarding any dangers attending the treatment of pneumonia by pilocarpine. It elicited in The Lancet of August 8th an account of one death under this treatment, the patient being a man in an early stage of the disease who suddenly developed dyspnœa followed rapidly by collapse and heart failure unchecked by atropin and cardiac stimulants. A case under my care might perhaps throw some light on the cause of this. A commanding officer of a military post in South Africa suffering from a common catarrh took one night one-third of a grain of pilocarpine with benefit and the next morning he took one quarter of this dose—i.e., one-twelfth of a grain—and proceeded to his duties about the camp. Although the dose was so small he was soon in a condition of dyspnœa which compelled him to lie down for the rest of the morning but he was well again in the afternoon This result following on one twelfth of a grain when he had taken with benefit four times as much as on the previous night (I was careful to make a correct entry of the doses) seems to show the danger of any impediment of any kind, even mental or social besides physical, to vigorous expectoration after taking pilocarpine even in small doses. In the case of this gentleman engaged in his duties about the camp reasons certainly not physical but mental or social prevented vigorous expectoration; at least, I can think of no other cause for the result.

SALOP INFIRMARY, SHREWSBURY.

A FATAL CASE OF RAYNAUD'S DISEASE.

(Under the care of Dr. Edward Cureton.)

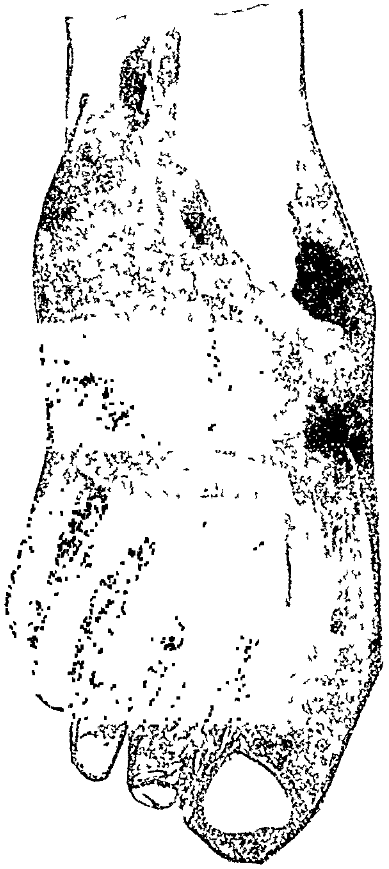
For the notes of the case we are indebted to Dr. E. W. Strange, late house physician.

The patient, a man, aged 35 years, was admitted into the Salop infirmary on Feb. 1st, 1904, with the following history. He was a striker at an iron foundry and thus was often exposed to great changes of temperature. As long as he could remember he had been subject to attacks of numbness in his fingers which were much more frequent in cold weather and came on if he put his hands into cold water or went out suddenly into the cold air. He said also that his mother and brothers were subject to similar attacks. His description of an attack was as follows. His fingers became suddenly cold as far as the proximal interphalangeal joints and he had a feeling of numbness with this and for a time the fingers were useless. Frequently both hands were affected but sometimes only one or two fingers on one hand. At first his fingers were white and the duration of this stage varied from two to twenty minutes. They then became slate coloured and this stage lasted from one to eight minutes. In both this and the first stage his tactile sense was greatly impaired. He said that he had often picked up articles at this period of an attack and found his fingers seemed very large and clumsy. They then became purple and lastly red. During this final stage he had a feeling of pins and needles. His fingers remained red for five or six minutes and then gradually resumed their normal colour. The whole attack varied in length from five minutes to three-quarters of an hour. He often perspired a great deal during an attack. The change of colour always began at the tips of his fingers and gradually spread upwards. He had noticed that sometimes after an attack he had difficulty in bending his fingers. His feet had always been apt to become cold but the attacks were never as bad as in his hands. Until January, 1904, the attacks in his feet did not cause him any trouble. He was at that time suffering from a severe cold which he had had for eight or nine days and on the morning of Jan. 23rd, which happened to be very cold, he had gone out to see his medical adviser. He woke up at 2 A.M on the 24th feeling as if he had lost the big toe of his right foot. On looking at it he found (to use his own expression) "that it was as white as milk and as cold as a stone," all sensation in it being lost. He rubbed it and about 7 A M. the colour began to return in it, whilst at the same time it became very painful. After this it did not trouble him again until the following night when he had another attack of a similar kind, and on the 28th the big toe of his left foot began to be affected in the same way. The attacks became more numerous, especially on the right side, and on the 29th were nearly continuous. He had gnawing pain in the intervals. Since then his attacks had not been quite so frequent. He said that when he was ill with the catarrh his urine was of the colour of pickled cabbage. It is, therefore, highly probable that at this time he was suffering from hæmoglobinuria.

---

[1] Medical Treatment, vol. i., p. 272.

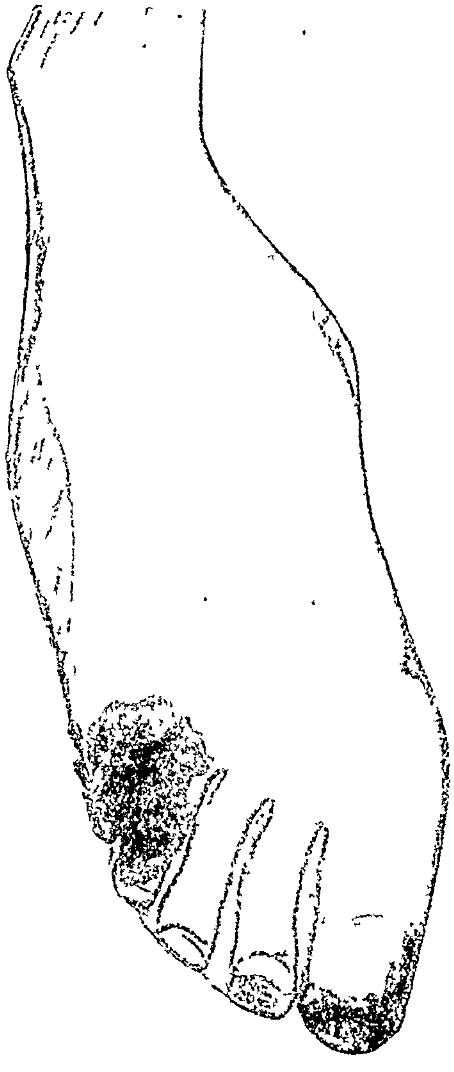
FIG. 1.



Right foot, Feb. 6th.

On admission the attacks were present in his right foot, across the proximal ends of the toes. He had no feeling in the big toe of his right foot which was quite gangrenous. Over the rest of the foot he had a greatly increased sense of pain (a pin prick causing him great agony). The skin over the big toe at its last joint was dark blue. Above this and at the base of the other toes the skin was of a bright red colour. The superficial veins over the front of the leg were dilated. The other foot was normal in colour and he had no pain in it. His alimentary and respiratory systems were normal. His heart was of normal size and no adventitious sounds were present. His pulse was 90 and regular and his arteries were not thickened or tortuous. He had some scleroderma on the palms of his hands and also slightly on the soles of his feet. His sensation was normal except in his hands and feet during an attack when tactile sensation was diminished. He also had a greatly increased

FIG. 2.



Right foot, Feb. 7th.

sense of pain in his right foot; his appreciation of heat and cold was normal. The plantar reflexes were absent and the knee reflexes were very much diminished. He had tremors of his hands and tongue and his wife said that he was a very nervous man. No eye symptoms were present. His urine was acid, with a specific gravity of 1025; there was no deposit and it contained no blood or albumin.

The patient's blood was examined by Dr. T. Law Webb who has kindly allowed Dr. Strange to publish his report which was as follows: "Red corpuscles, 3,000,000 per cubic millimetre; white corpuscles, 54,542 per cubic millimetre; hæmoglobin, 70 per cent.; and colour index, 1·16. The white corpuscles were made up as follows: polynuclears, 33272; small lymphocytes, 4363; large lymphocytes, 2181; eosinophiles, 12545; mononuclears, 1636; transitional, 500; and mast cells, 45; so that the patient had a colour index above 1 and also a very large increase in the number of eosinophiles. The percentage number of white corpuscles was: polynuclears, 61; lymphocytes, 12; eosinophiles, 23; and mononuclears, 4."

The patient was put to bed and kept as warm as possible, his feet being wrapped up in wool. He was given liquor trinitrini and potassium iodide and for his pain when an attack was in progress nepenthe was administered. On Feb. 6th his right foot was very red and inflamed (see Fig. 1) and was very painful. On the 7th it appeared to be much better and was of a light pink colour except the big toe and two outer toes which were blue (see Fig. 2). On the 8th, as he did not appear to be getting any better, injections of strychnine and liquor trinitrini were given and this time he also had pain of a spasmodic character in his abdomen and complained that his ears got cold and numb. On the 9th he still complained of a great deal of pain and his right foot did not look so well. The skin had by then died over the fourth and fifth toes, also there were some necrotic-looking areas over the dorsum of the foot, as shown in Fig. 3. The same morning he had pain again in his left foot which was not discoloured and was quite warm. At night the right foot was so painful that lead and opium fomentations were put on and injections of morphia were given hypodermically. On the 10th the foot was looking worse and he suffered much pain. The leg from the ankle to the knee was painted with glycerine and belladonna. On the 11th his leg felt better but he was delirious in the evening with pupils dilated widely. The glycerine and belladonna were discontinued. On the 16th the man looked worse and the gangrene of the right foot had spread. As he was suffering great pain he was given liquor opii sedativus and potassium bromide every four hours. On the 17th the foot looked worse but he had no pain. His mind wandered a good deal during the night when his temperature went up to 103° F. It remained now continually above 100°. On the 20th the gangrene had spread as far as the ankle, it being always dry in character. Where the skin was left it was dry and white and the gangrenous portions were purple with a bright pink edge separating them from the healthy tissue above. On the 23rd a consultation was held and it was decided to amputate the right foot. At this time the big toe of his left foot was of a slate-blue colour. On the 24th the patient was very ill during the night, his temperature varying between 102° and 99°. On the 25th it was decided that he was too ill to bear an operation and he died the same afternoon Permission for a post-mortem examination was not obtained.

Right foot, Feb. 9th.

Remarks by Dr. STRANGE —For permission to publish the notes of the case I am indebted to Dr. Cureton and for the account of the interesting blood changes to Dr. Law Webb.

DURHAM COUNTY HOSPITAL.

A CASE OF DOUBLE MULTILOCULAR CYST OF THE OVARIES.

(Under the care of Dr. S. W. PLUMMER.)

THE patient, a single woman, aged 46 years, was sent to the Durham County Hospital by Dr. W. R. D. Daglish of Ferryhill on Oct. 5th, 1903. She had always been a healthy woman. Her menstrual history was quite normal, the menopause taking place two or three years before. About ten weeks previously to admission she noticed a swelling in the abdomen and had frequent micturition but with no pain. She was still able to continue at work. Eight weeks before admission she received an accidental blow from a man's elbow on the left side of the abdomen. This gave her great pain and she had to leave her work. She now had pain on micturition and the bowels, which formerly had always been regular once a day, became confined and she had to take aperients. The swelling rapidly increased after the blow, till on admission the physical signs were such as are shown on the accompanying diagram, the shaded portion representing approximately the dull area of the tumour.

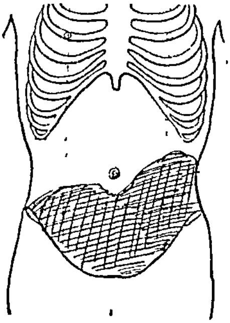

Diagram to show extent of the dull area.

On Oct. 9th the abdomen was opened in the middle line. There was a considerable quantity of free fluid in the abdomen. On passing the hand into it it was evident that a huge multilocular cyst had to be dealt with. No adhesions were to be felt and the incision was enlarged upwards beyond the umbilicus in order to deliver the tumour. On exploration of the tumour it was found to be divisible into two parts at the sulcus marked in the diagram The finger easily separated some soft adhesions and when the mass was lifted out of the abdomen it fell apart into two typical multilocular cysts of the right and left ovaries, each with a broad pedicle. In order to facilitate delivery some of the larger loculi in each tumour had been emptied, the contents being characteristic of the condition. The right tumour was of about the size of the fœtal head at term, the left being half as large again and more irregular in form. The pedicles, which were easily defined (that on the left side having some soft adhesions to the adjacent bowel), were tied with stout Chinese silk by a Staffordshire knot and the tumours were removed. The abdominal wound was closed in layers in the usual way. The after progress was quite uneventful. The wound was dressed for the first time on the tenth day and being soundly healed all stitches were removed.

Remarks by Dr. PLUMMER.—I think a brief record of this case is of interest. So far as I can learn the presence of two such large and fully developed cysts springing simultaneously from either ovary is rare. Kelly[1] mentions that dermoid cysts are not infrequently associated with ovarian cysts of the opposite side. Though Dr. Daglish sent the case to me as one of ovarian multilocular cyst I confess that I had doubts about it till the abdomen was opened. The patient's appearance rather suggested a malignant growth than the "facies ovariana." Still less did I anticipate having to deal with two such large cysts or so easy an operation. For the clinical notes I am indebted to Mr. W. Pattullo, house surgeon, and to Dr. Daglish.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Effects of a Proteid Dietary (Raw Meat).—The Limitations of Leucocytosis as a Sign for Operation in Appendicitis.

A MEETING of this society was held on May 11th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. D. CHALMERS WATSON read a paper on the Effects of a Proteid Dietary and gave an account of the clinical and pathological appearances observed in an experimental investigation on the prolonged feeding of fowls—for 16 months —on a diet of raw meat. The research was intended to confirm, or otherwise, the recent work of Kionka on avian gout. The experiment was unsuccessful so far as the induction of gout was concerned. This negative result was itself of interest and this was enhanced by the changes incidentally observed in the thyroid, parathyroid glands, bone marrow, and other tissues in the non-tuberculous fowls and by the distinctive character of the reaction in a tuberculous subject. The main points to which attention was directed were, first, the absence of any indication of (*a*) gout, (*b*) renal disease, and (*c*) vascular disease; secondly, the variety in the clinical features observed in the different subjects (the clinical symptoms involved mainly the cutaneous and nervous systems); thirdly, the changes in the thyroid (hypertrophy) and parathyroid glands (hypertrophy) and bone marrow; and fourthly, the very favourable manner in which one fowl affected with well-marked tuberculosis was influenced by the diet. The application of these facts to disease was shortly discussed under the following headings: first, the rôle of a proteid dietary—a diet rich in nucleins—in the induction of gout; and, secondly, the dietetic treatment of tuberculosis with special reference to the use of raw meat as a curative agent.—The PRESIDENT asked whether the excreta had been examined and analysed. He doubted whether the mechanism for the elimination of uric acid and urea in the fowl was altogether comparable to the renal excretion in man. He asked whether the meat taken was passed through the intestine incompletely digested, for it had been shown that such was sometimes the case in men fed on a meat diet. He asked whether there was any evidence that the fowls suffered from scurvy. He said that it had been observed in man that a raw meat diet was beneficial in tuberculosis.—Mr. WALTER EDMUNDS said that the microscopical specimens of the thyroid gland showed a marked increase in the size of the vesicles. This was the first instance, so far as he knew, in which an enlarged thyroid had been produced experimentally.—Dr. WATSON, in reply, said that he had not analysed the excreta of the fowls fed on an exclusively meat diet but that Kionka had made such an investigation. It did not, in his opinion, yield any satisfactory result. He thought that fowls had an equal capacity of dealing with an increase of uric acid as man had of dealing with urea. None of the fowls had manifested any evidence of scurvy.

Dr. HERBERT S. FRENCH read a paper on the Limitations of Leucocytosis as a Sign for Operation in Appendicitis. The paper was based on a study of the leucocyte counts in 83 consecutive cases of appendicitis in Guy's Hospital. The cases had been arranged in four main groups, the classification being based upon the character and course of the disease in each case and not upon the leucocyte changes. The four groups were: first, those with local signs and no tumour, spontaneous recovery; secondly, those with local signs and a definite tumour, spontaneous recovery; thirdly, those with local signs and a definite tumour, evacuation of pus; and, fourthly, those with general peritonitis. The leucocyte counts were recorded for each of the cases in every group and it was found that many cases in which spontaneous recovery occurred, without clinical signs of rupture of an abscess into the bowel, gave leucocyte counts exceeding 20,000, a few exceeding 30,000. Many cases in which pus had to be evacuated gave low leucocyte counts. Therefore, the leucocytosis alone could not be taken as a proof positive of pus, or of its absence, when it did not exceed 30,000. Many cases in which pus was present showed from 35,000 to 56,000 leucocytes, however, and no simple case reached these figures. A leucocyte count, therefore, of 35,000 or more could be regarded as strong evidence of pus, though lower figures left the question doubtful. More important than the total count was the rising of leucocytosis when counts were made at intervals. No such rising count occurred in any simple case; pus was present whenever successive counts showed increasing numbers. The reverse was not true; sometimes pus was present, though successive leucocyte counts showed progressive diminution. The sign, therefore, was valuable but had great limitations; it might mislead if attention were paid to it alone. It must be taken into account but only in association with the pulse-rate and the general condition of the patient. It was one of several clinical signs, variable like the rest, but often of great value in a difficult case.—Mr. L. S. DUDGEON said that in the examination of the blood for leucocytosis it was necessary (1) to count the number of leucocytes; (2) to make a differential count; and (3) to stain a blood film in a special method. The rise in the number of leucocytes was not necessarily an indication of pus. Even when between 20,000 and 30,000 were found it was not absolute proof of suppuration. He considered the differential count was most important, for the polymorphonuclear neutrophiles, which usually were about 65 per cent., rose to from 80 to 90 per cent. and in one case as high as 99 per cent. He did not consider that the special selective stain described by Ehrlich was of much value. He thought that if there was a leucocyte count of 30,000 with 80 per cent. polymorphonuclear neutrophiles or 15,000 leucocytes with 90 per cent. polymorphonuclears the probability of pus being present was very great, though even this was not absolutely diagnostic. In intestinal obstruction the leucocytosis might reach a very high figure, even as high as 50,000 or 80,000.—Dr. G. NEWTON PITT referred to a case of appendicitis with pylephlebitis which gave no increase in the number of leucocytes. The infection was due to the bacillus pyocyaneus.—Dr. FRENCH replied.

MEDICAL SOCIETY OF LONDON.

A Study of a Case of Rheumatic Fever.—The Influence of Early Operation on the Mortality and Results of Appendicitis.—Election of Officers.

A MEETING of this society was held on May 9th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

A general meeting was first held to receive the annual reports of the council, librarian, and chairman of the house and finance committee. Certain alterations were made in the laws of the society and two auditors were appointed to audit the balance-sheet for the year ending Sept. 30th.

At the ordinary meeting which followed Dr. F. J. POYNTON communicated a paper entitled "A Study of a Case of Rheumatic Fever." The first part of the paper described the clinical details of a fatal case of rheumatic fever in a child, aged nine years. The child had been under Dr. Poynton's observation at intervals for over a year and had twice been an in-patient in the Hospital for Sick Children, Great Ormond-street—on the first occasion with chorea in July, 1902, and on the second with the fatal illness in August, 1903. The cause of death was malignant rheumatic endocarditis attacking the mitral valve when in the early stage of stenosis. The necropsy was briefly described as were the bacteriological investigations which were made immediately after death. The post-mortem examination showed the absence of pericarditis and the presence of malignant mitral endocarditis. The diplococcus was isolated in pure culture from the mitral valve, the kidneys, and the spleen. Dr. W. Vernon Shaw with one of these cultures made experimental investigations and produced the lesions of rheumatic fever in rabbits and monkeys. The susceptibility of monkeys to this infection, as shown by Dr. Shaw, was a new and valuable point. A section of the mitral valve and specimens of the endocarditis produced in the animals were shown. Dr. Poynton claimed that this case afforded strong support to the infective view of the origin of rheumatic fever. It was the twenty-fifth of a series of fatal cases, of which he had investigated 24 with Dr. Alexander Paine. In the second part of the paper the practical bearings of the infective nature of rheumatic fever were commented upon. First, it became clear that it was as essential to study the early warnings of this disease as it was those of tuberculosis; secondly, it enabled them to speak with certainty of the existence of a truly rheumatic broncho-pneumonia and pleurisy, a rheumatic peritonitis, and a renal rheumatism; and, thirdly, the ability to produce with comparative constancy experimental heart disease marked a forward step in the history of the study of this condition. By the aid of this method it had been been shown that simple and malignant endocarditis might be phases in the same disease and that rheumatic fever was a cause of malignant endocarditis. Ante-mortem thrombosis and disease of the myocardium in rheumatic fever were also by the same method established as facts. The occurrence of infarction without visible valvular disease or clotting in the chambers of the heart had also been demonstrated—a fact which had close bearing on the pathology of chorea. The power to isolate an infective agent brought observers nearer to the chemical problems of rheumatic fever. Triboulet, Walker and Ryffel, Shaw, and Berger had already investigated the acids that were formed by the micro-organism. But not only did this view enable them to establish facts, it also threw out suggestions to guide them in unravelling some of the more difficult problems of rheumatism. The possibility that the micro-organism might remain latent in the tissue—a very reasonable one—threw light upon all chronic and relapsing rheumatic affections. That rheumatic fever was the result of an infection pointed, in Dr. Poynton's opinion, very strongly to the probability that a study of bacterial poisons would throw light upon gout and would enable observers to escape from the narrow views of that disease founded upon the uric-acid theory. Then, again, it would now be possible to reconstruct the skeleton of "rheumatism" from a study of the cardinal lesions of rheumatic fever. These cardinal lesions were in their structure similar; the nodule, the endocarditis, the pericarditis, the pleurisy, and the arthritis showed similar changes in their tissues. It was possible, then, that the deviations from this type would be comparable. Lastly, the treatment of rheumatic fever and rheumatism was advanced, not by the brilliant discovery of some antitoxin, it was true, but, nevertheless, quietly and surely. Thus the active phase of the disease and the active phase of the resistance to the disease were now more easily traced and the proper time at which to use hydropathic measures, radiant heat, massage, and electricity was more easily seen. Surgical measures undertaken for the treatment of severe arthritis rested on a surer basis and it was equally clear that, since the first site in which the micrococcus was deposited was not the synovial fluid but the synovial membrane, all hasty surgical measures were out of place. But it was in the prophylaxis of rheumatic fever that this view was of the greatest importance. In Dr. Poynton's opinion the time had come thoroughly to reinvestigate the causation and prevalence of rheumatic fever as an infective disease and he maintained that such a step would lead to the prevention of much organic heart disease among the children of the poor. —Dr. A. E. GARROD remarked on the confirmation which Dr. Poynton's paper gave to the infectivity of rheumatism. The opinions on the pathology of gout were constantly undergoing change, but it was difficult to accept the view of its infectivity. He (Dr. Garrod) was rather inclined to go back to the older uric acid theory of gout.—Mr. A. MARMADUKE SHEILD, speaking of the surgical aspect of such cases, remarked that some cases were extraordinarily benefited by opening and washing out of the joints, as originally adopted by Dr. J. O'Conor of Buenos Ayres. This method was also efficacious in cases of gonorrhœal arthritis and this suggested that the microbes and toxins were largely shed into the synovial fluid of such joints.—Dr. PAINE suggested the propriety of using urinary antiseptics in cases of rheumatic fever, both as therapeutic and prophylactic agents.—Dr. B. L. ABRAHAMS had examined the post-mortem records of the Westminster Hospital and found several types of rheumatic endocarditis. Salicylates reduced the joint swelling and the pain in rheumatic fever, but he doubted if they were really curative.—Dr. POYNTON replied.

Mr. W. H. CLAYTON-GREENE read a paper on the Influence of Early Operation upon the Mortality and Results of Acute Appendicitis. Tables of results in 202 cases were submitted. The following conclusions were arrived at: (1) that not only was the number of cases of appendicitis greater than formerly but the disease was increasing in severity; (2) acute appendicitis could not be dissociated from some degree of peritonitis; (3) there were four main forms of peritonitis, two of which were slight and two serious, and there were no data for determining which variety would occur; (4) the results of early operation showed not only a diminished death-rate but also fewer sequelæ; and (5) the mortality apart from the early operation was probably not under 20 per cent. and this figure was unpleasantly high.—Mr. A. E. BARKER congratulated Mr. Clayton-Greene on his painstaking researches but confessed that he (Mr. Barker) was unable to derive much clinical help or guidance from statistical methods applied to this subject.—Mr. SHEILD remarked on the complexity of cases of appendicitis and the impossibility of grouping them satisfactorily. In cases which set in suddenly and severely there was nearly always grave mischief and early operation was called for; so also in young subjects. He was more and more convinced that early operation was a safeguard though no doubt some cases were thus operated on which would have got well without.—Mr. W. MACADAM ECCLES concurred with the last speaker. The stage at which the case came under observation was a most important factor; many cases were, however, brought from a considerable distance.—Dr. H. A. CALEY referred to some comparative returns he had obtained from medical and surgical wards. He advocated operation at the earliest possible moment.—Mr. J. D. MALCOLM referred to a case illustrating the complexity of the subject.—Mr. CLAYTON-GREENE replied.

The result of the ballot showed that the following gentlemen had been elected for the session commencing October, 1904:—President: Mr. J. Langton. Vice-Presidents: Dr. C. E. Beevor, Mr. B. Pitts, Dr. E. J. Nix, and Mr. Charters J. Symonds. Treasurer: Mr. D. H. Goodsall. Librarian: Dr. A. F. Voelcker. Honorary secretaries: Mr. H. J. Waring and Dr. J. S. R. Russell. Honorary secretary for foreign correspondence. Dr. H. D. Rolleston. Council: Mr. A. E. Barker, Sir Hugh R. Beevor, Dr. J. V. Bell, Mr. C. C. Braine, Dr. H. A. Caley, Mr. Albert Carless, Dr. C. W. Chapman, Dr. H. Corner, Dr. Lovell Drage, Dr. F. de Havilland Hall, Mr. Richard Lake, Dr. A. H. N. Lewers, Mr. T. H. Openshaw, Dr. F. S. Palmer, Dr. J. E. Ranking, Dr. A. H. Robinson, Mr. A. W. Mayo Robson, Mr. W. G. Spencer, Dr. G. C. Steele-Perkins, and Mr. C. S. Wallace.

OBSTETRICAL SOCIETY OF LONDON.

Sarcomatous Fibro-myoma.—Hæmatoma and Hæmatocele.

A MEETING of this society was held on May 4th, Dr. EDWARD MALINS, the President, being in the chair.

Dr. P. HORROCKS showed a specimen of Fibro-myoma undergoing Sarcomatous Degeneration removed from a patient 46 years of age; abdominal hysterectomy was performed owing to rapid growth of the fibroid in association with menorrhagia. He remarked that some authorities still disbelieved in the possibility of sarcomatous change in a fibromyoma of the uterus and referred to similar cases published by Doran and Finlay and to another previously published by himself.—Mr. ALBAN H. G. DORAN said that he doubted whether these tumours, said to be "sarcoma" histologically, were clinically malignant. One observer had in a large series of uterine fibroids made out malignant elements in 10 per cent. of all the cases, a proportion quite at variance with clinical experience. Mr. Doran suspected that the cells which were large and spindle-shaped, might be altered plain muscle cells. Histological elements of that kind when subjected to morbid influences assumed strange appearances, especially when a number were seen in section, cut longitudinally, transversely, and obliquely.

Mr. ALBAN DORAN read a paper entitled "Hæmatoma and Hæmatocele, a Study of Two Cases of Early Tubal Pregnancy." He said that it was generally taught that hæmatocele associated with interrupted early tubal gestation demanded operation whilst a hæmatoma or extraperitoneal hæmatocele under the same conditions would subside if the patient was kept at rest. Two cases which did not support this teaching were related and discussed at length. In the first case the patient passed clots over two months after the last period, pelvic pain set in, and a swelling could be detected in the right fornix and iliac fossa. A week later a decidua was expelled; then a mass with all the characters of a pelvic hæmatocele developed and became harder and smaller during prolonged rest. Menstruation was re-established within twc [illegible] was seized with [illegible] when a period was [illegible] set in. A swelling could soon be defined above the pubes; its lower limits formed a convex mass behind the cervix, simulating a hæmatocele in Douglas's pouch. This swelling arthritis. The arthritic deformities in the hip consisted of flexion, internal rotation, shortening, and adduction; in the knee of flexion, subluxation, and external rotation of the tibia; in the back, of a kyphosis sometimes preceded by a lateral deviation; and in the shoulder of elevation of the shoulder-girdle, adduction, and at a later stage of what Mr. Jones had described as a pathological subcoracoid displacement of the humerus. The spinal lateral deviation was very important clinically as it might be mistaken for scoliosis. In an early case of Pott's disease rigidity would be present. In lateral curvature rigidity was only present in the later stages where rotatory changes had occurred. As regards the treatment, the principal object was to protect from deformity, or if it had appeared to correct it; to immobilise the joint and so to relieve the muscles from spasm and then from contracture; to prevent bone destruction due to both attrition and pressure; and to relieve the joint from weight bearing. The all essential treatment was rest. For small children Mr. Jones employed a double splint as it was easier to apply and simplified nursing. In this frame the child was kept until all signs of disease were gone and the child was made to live in the open air. Such early cases improved generally, many recovering with moveable joints after the application of the splints for two years and it was rare to find a flexion deformity of more than 10°. Extension was hardly ever employed in early cases and the so-called night-jerks were hardly seen. The neglected child whose disease was more advanced and whose deformity was considerable presented some difficulties. The deformity was corrected under an anæsthetic. A direct pull by means of a thick skein of wool and counter extension by a sheet and division of the adductors, if tense, would generally equalise the so-called practical or apparent length of limb. The correction consisted in overcoming flexion and adduction and lowering the pelvis on the diseased side. Once in the abductor frame the limb was kept at absolute rest and the constant muscular pull upon the head of the femur, as evidenced by ever-increasing deformity, was overcome. Where the deformity was less marked the application of an abduction frame was sufficient. Generally speaking, Mr. Jones did not open tuberculous abscesses because the operation was incomplete if it could not remove the disease of which the abscess was but a symptom. If, however, with the presence of fluid there were discomfort, pain, and pyrexia, and if the patient was rapidly or steadily declining in condition, then the abscess might be incised and antiseptic irrigation adopted. Amongst the poor Mr. Jones had found nothing better as a dressing for abscesses than medicated sawdust. In the case of the hip the splint was kept on until consolidation of the structures was apparent, all deformity was gone, and the pelvis was lowered on the diseased side. Abduction should always be aimed at to compensate for shortening, the abducted limb being gradually brought towards the sound side and the double frame changed for a Thomas's hip splint. Walking should be allowed aided by patten and crutches. Although many joints recovered movement, Mr. Jones preferred an ankylosis to occur in severe cases, especially in the hip, the knee, and the ankle. Cases of active disease of the knee with marked flexion were placed in a Thomas's knee splint and could be straightened wholly or in part at once or by the pressure of a pad. This was much better than the weight and pulley. Subluxation of the tibia backwards was a most obstinate deformity and might even require a V-shaped excision for its treatment. The position of greatest utility should always be aimed at. This, in the hip, was abduction and full extension; in the knee, extension; in the ankle, an angle of 95°; in the wrist and spine, hyper-extension; and in the elbow, usually an angle of about 40°. In the treatment of spinal caries, even with the best mechanical means, it was difficult to influence curvature, especially so in the lower cervical and upper dorsal regions.

The PRESIDENT, Mr. C. W. MACGILLIVRAY, Mr. C. W. CATHCART, Dr. WILLIAM TAYLOR, Mr. DAVID WALLACE, Mr. H. ALEXIS THOMSON, and Dr. D. CHALMERS WATSON took part in the discussion which followed.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on April 15th, Dr. C. O. Hawthorne being in the chair.—Dr. James Taylor showed a boy aged five years with Congenital Proptosis and Meningocele. The mental condition was defective, recently his eyesight had been failing, and nystagmus and optic atrophy were also present.—Mr. Sydney Stephenson said that a mechanical factor was probably the cause of the neuritis as well as of the proptosis and divergence of one eye which were constant features of such cases.—Dr. J. Anderson Smith showed a girl, aged five years, who at the height of an attack of measles developed cerebral symptoms—namely, vomiting, squinting, retraction of the head, photophobia, and unconsciousness. At the end of five days the acute symptoms subsided but she was found to be aphasic, resented being touched, and wasted rapidly. There was no optic neuritis or ear trouble. A month later she was still aphasic, could not sit up in bed, moved her limbs in an ataxic manner, and appeared to have general cutaneous anæsthesia. There were slight rigidity of the limbs, ankle clonus, and exaggeration of the knee-jerks. More recently there had been gradual improvement in the motor power, she could say a few words, the ankle clonus had disappeared, and sensation was improving.—Dr. Hawthorne thought that the evidence of meningitis was not clear and suggested that the symptoms might have been due to some form of toxin. He recalled a somewhat similar condition in an adult after influenza.—Dr. Taylor agreed as to toxæmia connected with the measles being the probable cause.—Mr. Stephenson showed two cases of Microphthalmos, one slight, in a boy aged six years, and the other extreme, in a girl aged 16 months. He pointed out that a few years ago the latter would have been called a case of anophthalmos, because no eye was visible on opening the lids and it was only on deep palpation that a small pea-like body could be felt towards the back of each orbit. These small bodies in all probability represented rudimentary eyeballs, containing more or less immature nervous elements, and upon that ground he preferred to regard the case as one of microphthalmos.—Dr. E. P. Baumann showed two cases of Anæmia. The first was in an infant ten months old, who was obviously syphilitic and had an enlarged spleen. Blood examination showed merely the existence of a severe secondary anæmia. He considered the whole of the symptoms as secondary to syphilis. The second case was that of a girl, aged one and a half years, without evidences of syphilis, but with an enlarged spleen. Blood examination showed a well-marked leucocytosis and also a large number of nucleated red cells, a considerable proportion of which were megaloblasts. The case was probably one of pernicious anæmia in infancy.—Dr. A. Morison showed a case of Dactylitis with Subcutaneous Nodules in an infant aged 16 months. He regarded the case as tuberculous.—Dr. S. Vere Pearson showed as a case of Tuberculous Nodule in the Ponto-Medullary Tract a boy, two years old, who was suffering from weakness in, and disinclination for, walking, slight drowsiness, and squint in the left eye. There had been occasional retching and difficulty in walking. Definite right-limbed paresis—i.e., crossed paresis—had developed later.—Dr. E. Farquhar Buzzard referred to the rarity of tuberculous tumours in this region and to the fact that they were usually discovered accidentally after death, having produced no symptoms during life. He was inclined to regard the case as one of pontine tumour, probably gliomatous.—Dr. Hawthorne showed a boy, aged ten years, suffering from Paramyoclonus Multiplex. There were sudden, shock-like, clonic muscular contractions affecting both sides of the body at the same time. The bilateral and isochronous character of the contractions was well seen in the cremaster muscle. The muscles of the face, the trunk, and the thighs were also affected.—Mr. Leonard A. Bidwell read a paper on a case of Gonorrhœal Pyosalpinx in a girl, aged six years, treated by removal of the tubes.—Dr. George Carpenter read a paper on a case of Gonorrhœal Inflammation of the Uterine Appendages in a girl, aged three years, with spontaneous recovery.—Mr. R. C. Dun read a paper on a case of Post-hemiplegic Chorea, Petit Mal, and Mental Irritability treated surgically.—Mr. Bidwell read a paper on two cases of Strangulated Hernia in infants under one month old treated by operation.

GLASGOW NORTHERN MEDICAL SOCIETY.—A meeting of this society was held on May 3rd.—Dr. J. Galbraith Connal showed several cases illustrating Secondary and Tertiary Syphilitic Disease of the Throat and Nose and made remarks upon them. Photographs were also shown of a case with marked Nasal Deformity due to Syphilitic

Disease which was remedied by paraffin injection. The apparatus for the injection of paraffin was also shown. Dr. Connal advocated the use of paraffin of high melting-point.—A hearty vote of thanks was given to Dr. Connal for his interesting demonstration.—Dr. Alexander Johnston next read a paper entitled "Observations on the Value of the Widal Serum Reaction in Enteric Fever." He confined his remarks chiefly to the value of the reaction in aiding the recognition and notification of enteric fever in general practice. Of the cases of supposed enteric fever sent to hospital there was an error of only 16 per cent., a result which he considered very creditable to the practitioners. Of those which proved to be not enteric fever a considerable proportion were tuberculous in character. A few cases also, which were sent in under other diagnoses, particularly scarlet fever, were found to be cases of enteric fever. The Widal reaction consisted of the cessation of motion and agglutination of organisms when a small quantity of blood was mixed with them which had been taken from an infected animal. Blood was drawn from the lobe of the ear, caught in a sterilised tube, and taken to the laboratory. Here it was mixed with the active bacteria and if the patient from whom the blood was drawn were suffering from typhoid fever agglutination occurred. Points of importance in performing the test were that the blood must be diluted, the test culture must be young and pure, and there must be a time limit. The standard dilution was 1 in 50, the time limit was one hour, and the culture was one of less than 24 hours' old. In looking over a series of more than 300 cases four groups might be differentiated: (1) cases clinically enteric fever, yielding a positive reaction—over 240 cases; (2) cases clinically not enteric fever, yielding a positive reaction—about 30; (3) cases clinically enteric fever, yielding a negative reaction—some two cases; and (4) cases not clinically enteric fever, yielding a negative reaction—about 30. Probable sources of error were the existence of paratyphoid forms and late development of the agglutinating reaction, possibly appearing after the second or third week or during convalescence. A positive reaction might be obtained in those suffering from some other disease who had already had typhoid fever. The accuracy of the test was probably from 90 to 95 per cent. but in everyday practice with cases in the early stages there was probably an error of about 17 per cent.—Several questions having been asked by members and answered by Dr. Johnston he was accorded a hearty vote of thanks by the members of the society.

ERRATUM.—In the report of the meeting of the Wigan Medical Society on p. 1209 of THE LANCET of April 30th it should have been stated that the address on Ankylostomiasis was read by the President, Mr. J. Chronnell, and not by Mr. William Mitchell Roocroft.

Reviews and Notices of Books.

Nervous and Mental Diseases. By ARCHIBALD CHURCH, M.D., Professor of Nervous and Mental Diseases in the Chicago University Medical School; and FREDERICK PETERSON, M.D., President of the State Commission in Lunacy, New York. With 338 illustrations. Fourth edition, thoroughly revised. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 922. Price 21*s.* net.

THE first edition of this important work, which embodies some of the best features of neurological and psychiatrical study in America, was published in 1899. The present (fourth) edition has been considerably enlarged and new material added both in the sections of nervous and of mental disease, while the text has been revised throughout and a number of new illustrations have been added. The first 600 pages are devoted to the section on Nervous Diseases by Dr. Church, while the concluding 250 pages of text, dealing with Mental Diseases, are the work of Dr. Peterson. The section on nervous diseases constitutes an ideal text-book on the subject and would serve as an excellent introduction to the larger works of Gowers and Mills. It deals systematically and instructively with such subjects as the clinical examination of patients, electric reactions of the muscles and nerves, disturbances of the senses and of speech, diseases of the cerebral meninges and the cranial nerves, and diseases of the spinal meninges and spinal nerves. The various individual diseases of the brain proper and of the bulbo-spinal cord and all the general diseases of the nervous system, with or without known anatomical lesion, are then dealt with in the concluding part of the section. No disease of any importance seems to have been omitted. Here we find graphic descriptions of acromegaly and its allies, Raynaud's disease, intermittent limping, and the various cerebral and spinal palsies of adults and of children. Neurasthenia and hysteria receive adequate attention and so do the other neuroses—epilepsy, migraine, tics, and allied disorders—the chapters concerning these neurotic affections showing noteworthy powers of exposition and a masterly grasp of the subject. Disorders of sleep and hypnotism are briefly touched upon and Dr. Church remarks that "women should never be hypnotised without reliable witnesses." "The public use of hypnotism," adds Dr. Church, "can only appeal to the morbid. *In this connexion its power for harm is proven.*"

Dr. Peterson's contribution on mental diseases deals systematically with the general etiology, general symptomatology, and principles of treatment of mental disease. A valuable critical review, suitable mainly for the mental digestion of the advanced student of psychiatry, from the pen of Dr. Adolf Meyer, director of the Pathological Institute of the New York State Asylums, is intercalated in the text and deals in a masterly and discriminating fashion with recent problems of psychiatry. This is an article of 40 pages in small type reviewing minutely the advances of the past two decades in the higher and more refined departments of investigation—viz., clinical analysis, psychopathology, localisation of functions, the "lines of march" of the various insanities, the correlation of cerebral lesions and morbid processes with psychological disturbances, and the scientific classification of mental disease. The student will find much here to think and to ponder over and much that will, if he appreciates it aright, broaden his horizon and clear his insight into the sphere of mental disease. The different types and varieties of insanity are then dealt with *seriatim* by Dr. Peterson. They include all the common forms, ranging from paranoia and the higher psychoses down to idiocy and imbecility. Many reproductions of photographs and illustrations are added which increase the value of the text. Within the limited space at his disposal Dr. Peterson has achieved a decided success in his exposition of mental diseases. The book can be strongly recommended to the practitioner, the alienist, and the serious student of the nervous system and the mind.

Functional Diagnosis of Kidney Disease. By Dr. LEOPOLD CASPER and Dr. PAUL F. RICHTER. Translated by Dr. R. C. BRYAN and Dr. H. L. SANFORD. London: Rebman, Limited. 1903 Pp. 233. Price 7*s.* net.

THIS book, which was first published in Germany some two years ago, owes its origin to advances in physical chemistry and to the introduction of ureteral catheterisation. The problems which the authors attempt to solve are the following: "How are we to gain an idea of the amount of the total work done by the kidneys and how shall we decide whether this amount of work is sufficient or insufficient for the body? How shall we learn how the work of the kidneys is divided, how shall we definitely decide how much work each kidney does?" The answers to these questions are afforded in a logical manner. It will be seen that these problems are precisely those recently discussed in our columns,[1] where a full description was given of the instrument devised by Dr. Georges Luys for intravesical separation of the urine coming from each kidney. Various modes of examination are discussed before the authors reach the conclusion that "catheterisation of the ureters is the one method which will come nearest to accomplishing our purpose," although they admit that it cannot meet the needs of every case. They do not allow that this practice involves any danger, while as to any difficulty, if a surgeon feels unequal to the task "he must call in someone else who can do it for him." The third chapter, which is the longest, deals with the methods of *functional kidney diagnosis* and this supplies adequate information of recent researches connected with the elimination of nitrogen, of chlorides, and of artificially introduced substances like methylene blue. In separate sections the combined work of both kidneys and the determination of the work performed by each kidney are duly considered. Notes of 90 cases examined by the authors are appended to illustrate the value of the results attainable by catheterisation of one or both ureters and to indicate the importance of the contention that before undertaking operations upon the kidney it is desirable to estimate accurately the nature of the work performed by each kidney. This fact has long been recognised but the authors have done good service in demonstrating the comparative ease with which this information can be obtained in every case. The book is well printed, and, as a rule, well translated, though in a few places long and involved sentences betray its foreign origin.

---

[1] THE LANCET, March 26th, 1904, p. 850.

The Therapeutics of Mineral Springs and Climate. By I. BURNEY YEO, M.D., F.R.C.P. Lond. London: Cassell and Co. 1904. Pp. 760. Price 12*s.* 6*d.* net.

IN Dr. Yeo's treatise on "Clinical Therapeutics," the revised edition of which has but recently appeared, the practitioner will find a rich storehouse of facts garnered from a long experience; in his work on "Food in Health and Disease" all the questions connected with that subject are fully considered; and now the author in the book under review furnishes the medical profession with a very complete guide to the therapeutics of mineral springs and climates. He has long been an authority on the use and selection of baths and climates in the treatment of disease and some years ago published a work on the subject. The present volume has grown out of the former and enriched with his larger experience it forms a very useful guide to all the chief baths in Europe.

The work is divided into two parts. The first is devoted to the study of mineral springs and the second to the subject of climates. The first part opens with certain general considerations of mineral springs, such as their nature and definition. Dr. Yeo defines a mineral or medicinal water as one which either from its chemical composition or its thermality, or some other quality which experience has proved it to possess, is found useful in the treatment of disease. The composition of these springs generally is then spoken of: salts of lime, of sodium, and of magnesium, iron compounds in small amounts, and silica are most frequently met with; other metals which are less common are detailed, as are also the organic substances and gases. It is pointed out how the thermality of the springs varies, some being extremely hot, whereas others, as the Evian waters, are cold. With regard to the classification of these various springs Dr. Yeo divides them into the following groups: (1) simple or indifferent; (2) common salt; (3) alkaline with its three subclasses of (*a*) simple alkaline, (*b*) alkaline and common salt, and (*c*) alkaline and sodium sulphate; (4) bitter; (5) iron or chalybeate; (6) earthy or calcareous; (7) sulphur, including sodium sulphide, sulphuretted hydrogen, and sulphur and sodium chloride water; and (8) arsenical, containing (*a*) arsenious acid and (*b*) arsenates. The author next describes the modes of application and action of mineral waters in a general sense. Waters may be applied externally or taken internally, both methods being employed in the majority of cases. As regards their general action, it is shown that none of their constituents is absorbed by the skin as was formerly thought. The simple thermal baths merely dilate the skin capillaries and thus promote the cutaneous blood circulation; if, however, the waters contain chemical elements stimulating the skin then additional effects are produced. Ample information of the effects thus excited by the various waters is given, whilst the chapter is completed by an account of the internal action of the waters. In Chapter III. medicated baths, pine-needle baths, peat baths, mud baths, sun baths, electric-light baths, and others are dealt with. The description of the principal medical springs follows and the obviously convenient plan of giving the particulars of the various mineral-water resorts in alphabetical order has been adopted, thus the practitioner can at once find details concerning any spring. In the description of each spring the reader is supplied with the chemical constitution of the water, the names of the maladies most suitable for treatment by it, its "season," and many other details.

We next come to one of the best chapters in the book—viz., the Counter-indications and Indications of Mineral Waters and Baths in the Alleviation and Cure of Disease. As regards the former, *advanced* cardiac diseases, *advanced* arterio-sclerosis, hepatic and renal cirrhosis, and pulmonary tuberculosis are contra-indicated as are all forms of malignant and serious organic visceral disease, all maladies with a disposition to internal hæmorrhage, grave diabetes, aneurysm, true angina pectoris, and grave and recent affections of the central nervous system, together with confirmed cases of paralysis. Certain special contra-indications are also pointed out. The application of mineral springs to the treatment of various maladies is succinctly treated under the various diseases; of special value is the section referring to disease of the circulatory system, the Nauheim treatment being fully set forth.

Part II. refers to the subject of Climate and Climatic Results. The various factors composing a climate are first enumerated. The author divides climates into (*a*) sea or insular; and (*b*) inland or continental. The characteristics of sea and mountain air are then narrated and there follow a full account of the nature of the various seaside resorts in England and Wales, Ireland and Scotland, the continental seaside resorts, the Engadine, the Riviera, and other places. An excellent chapter on winter resorts is given. The work concludes with the consideration of the kind of climatic resorts suited to particular maladies. The treatment of tuberculous affections is critically examined, Dr. Yeo believing in the efficacy of "open-air" treatment at home. A list of the sanatoriums for "open-air" treatment terminates this valuable work.

Drugs: their Production, Preparation, and Properties. By H. WIPPELL GADD, Fellow of the Chemical Society; Member of the Pharmaceutical Society and of the Society of Public Analysts; Lecturer on Pharmacy and Materia Medica to the Royal Albert Memorial College, Exeter. London: Baillière, Tindall, and Cox. 1904. Crown 8vo, pp. xii.–180. Price 5*s.* net.

THE author states that the object of this work is to give a concise account of the principal vegetable, animal, and chemical substances used in medicine. He adds that it has been written principally for students and that it embraces all the drugs included in the Pharmacopœia or mentioned in the syllabus of the qualifying examination of the Pharmaceutical Society. The introduction, which is concerned with *definitions and classification, immediately arrests attention* with the statement, "All drugs are poisons." Although at once explained these four words may readily be seized upon and misapplied by those who question the benefit of any system of medicine. A book of this kind stands or falls according to the value of its classification. Mr. Wippell Gadd divides his material into three sections, concerned respectively with vegetable products, animal products, and chemicals. The subdivisions, however, are not so satisfactory. An attempt has been made to deal in turn with the parts employed, as roots, stems, leaves, flowers, and such like. Now this presents obvious difficulties when different parts of the plant are official and sometimes produces confusion—e.g., under the heading of "Hairs, Glands, &c.," we find cotton-wool, kamala, and cowhage, with no indication that the last is not official. The animal products are grouped according to the animals from which they are derived, hence milk-sugar and ox-bile stand together, and thyroid follows wool fat. In the table of contents appears a remarkable line which must be quoted to be appreciated duly: "*Fish Product.* Cod-liver Oil. Musk. Castor. Animal or Curd Soap. Leeches." Under Insects and Insect Products we meet with shellac, while galls appear some pages earlier among plant products. Frequently the student is assisted with the etymology of botanical or technical terms and when Greek is employed the Greek characters are followed by the same word in italics with accents, but unhappily there is lack of consistency, for on p. 25 we find χωλή, *chōlē*, bile, and on p. 95 appears χολὴ, *cholē*, bile. Salt of tartar, the synonym for potassium carbonate, is derived from *tartarus*, hell, while no explanation is given of tartar emetic, where the sense of the derivation would seem to be more appropriate and convincing. Evidently the author has wearied in the attempt to be instructive, for although he does honour to the French chemist Pelletier and to Dr, Rodie, he leaves "Hanburii" and "Lansdorfii" without any explanation. Under Tragacanth it is amusing to find a quotation from Robert Browning vaunting the excellence of Judæa's gum tragacanth and followed by the author's grave correction that "the gum is, however, collected in Persia." We can commend this book for the entertainment it affords at a moderate price.

LIBRARY TABLE.

The Physiognomy of Mental Diseases and Degeneracy. By JAMES SHAW, M.D. R.U.I. Bristol: John Wright and Co. 1903. Pp. 83. Price 3*s.* net.—This little volume by Dr. Shaw appears opportunely at a time when the subjects of physical deterioration and mental degeneracy are occupying the public mind. The limited nature of the study as regards its restriction to the physiognomy of the insane and of allied degenerates enables the subject material to be compassed within a small scope. Dr. Shaw's experience in public asylums has enabled him to give excellent descriptions, often illustrated with reproductions of photographs, of the physiognomy, gestures and attitudes, and general appearances of patients suffering from the various forms of insanity. The text is not limited to mere description of features and appearances of the insane and of degenerates allied to the insane but includes useful remarks and information on the causation of the characteristic anatomical features and anomalies of structure which are so abundantly present in such individuals. Some interesting reproductions of photographs of the ears, the teeth, and the palate are added, as these organs show frequent variations and abnormalities of development in the class of persons considered. Dr. Shaw's work will serve as a handy unpretentious elementary introduction to the subject of the physiognomy of mental disease and degeneracy.

Ailments of Women and Girls. By FLORENCE STACPOOLE, Lecturer for the National Health Society and for the Councils of Technical Education. Bristol: John Wright and Co. Pp. 238. Prices: boards, 2*s.* net.; cloth, 3*s.* net.—This book is an excellent example of its class. There are many matters concerning their health upon which women are only too often wofully ignorant and many of the illnesses from which they suffer are brought on by neglect of the very simplest precautions. Mothers are especially to blame in this respect and forget that their daughters require careful supervision and instruction in order that they may avoid many of the ailments peculiar to their sex. This little book treats in a simple and straightforward fashion of the various common ailments to which women are liable. The author is to be congratulated upon the clear manner in which she has described these various conditions and upon the excellent common-sense of her recommendations. There are many hints in the book which will be of value to medical men and it is one which we can cordially recommend to those for whom it is intended.

Insanity in Everyday Life. By E. G. YOUNGER, M.D. Brux., M.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1904. Pp. 109. Price 2*s.* 6*d.* net.—This useful little work aims at giving in brief compass the broad outlines of insanity as met with in general practice. The causes of insanity and the early and premonitory symptoms are briefly but clearly dealt with at the outset and the various matters concerning the certification and care of lunatics are referred to. A description is then given of the "types" and the special "forms" of insanity, the classification being based on old and well-worn but useful lines. The descriptions are marked by clearness of expression and due emphasis is laid on points of diagnostic and practical importance. "Borderland" forms of insanity are very briefly referred to, though they form the bulk of cases which pass through the hands of the practitioner before they reach the specialist in psychological medicine. The work certainly succeeds in what it professes to do—viz., in giving a concise, clear, and practical account of insanity and of lunacy law in so far as they concern the general practitioner. It is written in an easy, lucid, and readable style and would be useful also to the medical student attending a first course of lectures and clinical instruction in mental disease.

The Black-Country Nurse: Extracts from the Life of Nurse Sirrah. By LIZZETTEE. Pp. 63. Price 1*s.*—It is a comfort to a reviewer after a course of profound scientific works to come across such a simple and unaffected narrative as that presented in the work now before us. We call it simple but the writer makes great use of a figure similar to the rhetorical figure known as the paraprosdokian. She plunges *in medias res* by informing us that "Nurse Sirrah was when a child rather peculiar." Her name was Eliza and we must reluctantly pass over her early days until she had an offer of marriage, "but having heard such an indifferent account of the gentleman was sorry and was obliged to refuse him and his kind offer." After this she, while living with a dear old Christian lady, attracted a schoolmaster, a curate, a tinplate worker, an edged-tool grinder, and two tailors. However, Miss Sirrah would have none of them and went away to be trained as a nurse. She was trained near the river Mersey, then she went to Queen's Hospital, Birmingham, then to the Suffolk General Hospital, then to a little hospital in the Fens. Here the matron was a "very nice woman matron, ... very neat in her appearance, often being dressed in black silk, ... but unfortunately in a while she became tired of hospital life and left the institution to live with her daughter. They kept a ladies' school just for amusement." Nurse Sirrah eventually found herself at Poplar Hospital where the house surgeon "was a good and such a nice man. Miss C., Sirrah and all the rest were in love with him. But the callous young dog went one day and monopolised the heart of one of the visiting doctor's daughters. But he asked all the nurses for a likeness and gave them one of his own; and then went and got married." We are pleased to be able to state that the nurses, far from resenting this heartless conduct, "bought him a flower-stand from Mappin and Webb's, a silver stand with silver feet, and a glass bowl for the flowers. Sirrah and others filled it with choice flowers and presented it to the doctor who was very pleased with his wedding present." Nurse Sirrah seems to have been a passionate young woman, for when the new house surgeon was appointed, he was a nice-looking, dark-complexioned man, she "fell in love with him—so that was all right; she was well suited for a lover—in the house and another out of the house—a barber." Such goings on as these deservedly came to a bad end. The barber "used to furnish her with scent and hair improvers, and bear's grease, and scented pomade, and tooth powder, until she had all her teeth out and then he gave her up."[1] The house surgeon, however, "stuck to his attentions, found her medicine and a set of teeth, a walking stick, and an umbrella, and then left to marry the late house surgeon's wife's sister." After this double reverse Nurse Sirrah left Poplar and went to St. Thomas's Hospital where with many regrets we must leave her. Every nurse and every house surgeon should read this work. We have rarely come across any book which gives such a vivid picture of hospital life, not even Mr. Hall Caine's "The Christian." we cannot forbear from quoting the following dramatic episode as a finish: "So the assistant house surgeon became betrothed to the sister nurse of the children's ward. They married on pain of dismissal. Then the lady superintendent asked the head house surgeon to become betrothed to her. But the doctor replied, expressing his inability to compete, saying his engagements were so many and some so urgent that he could not possibly grasp such an enormous link to unite in matrimony, particularly with one who was a widow and herself a lady of rank."

Analytical Records

FROM

THE LANCET LABORATORY.

1) HEMISINE PREPARATIONS, "TABLOID," "SOLOID," AND "ENULE"; (2) "ENULE" QUASSIN, "ENULE" SOAP COMPOUND; AND (3) "TABLOID" VERONAL.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, HOLBORN, LONDON, E.C.)

1. Hemisine represents the active principle of the medulla of the suprarenal gland. The action of this principle, as is well known, is powerfully hæmostatic and it has been employed internally in hæmatemesis, hæmoptysis, and in cerebral hæmorrhage. It is suggested that hemisine is of greater therapeutic value than either digitalis or strychnine. The "tabloid" hemisine is suitable for internal administration and the "soloid" is useful for external application, the ophthalmic tabloid for ocular use, and the enule of hemisine for application in the rectum. It may be added that hemisine is used in the form of a spray in the treatment of hay fever and in inflamed conditions of the throat and nose. 2. Recent additions to the list of rectal suppositories known as the "enule" brand are "enule" quassin employed as an anthelmintic for the ascaris lumbricoides and "enule" soap compound containing equal parts of curd soap and dried sulphate of sodium, a combination that is useful for the relief of constipation. 3. Veronal is a hypnotic of comparatively recent introduction and already some favourable reports have been made in regard to its use. Its therapeutic action appears to be similar to that of trional but with more satisfactory results. Veronal is a synthetic compound which is chemically described as di-ethyl-malonyl-urea. Tabloids of veronal are made containing 0·5 gramme and 1 gramme respectively of the drug.

SCOTCH WHISKY.

(HENRY SIMPSON AND CO., GLASGOW, AND 6, CROSBY-SQUARE, LONDON, E.C.)

This spirit is characterised by a somewhat dark colour and the impression which it gives on tasting is that of a well-matured whisky. On analysis the following results were obtained: extractives, 0·15 per cent.; mineral matter, *nil*; alcohol, by weight 40·05 per cent., by volume 47·40 per cent., equal to proof spirit 83·07 per cent.; volatile acidity calculated as acetic acid, 0·024 per cent.; and fixed acidity calculated as tartaric acid, 0·015 per cent. As regards secondary products the following were the results given in grammes per 100 litres of absolute alcohol present: acidity calculated as acetic acid, 50·88; aldehyde, 17·65; furfural, 3·23; ethers calculated as ethyl acetate, 57·83; and higher alcohols, 212·70. The total secondary products are thus 342·29. According to these figures the spirit presents the composition of pure malt whisky. The taste is soft and mellow and there is an entire absence of harsh qualities.

DUTCH RUSKS.

(AGENCY: L. TERWINDT, LIMITED, 76, QUEEN-STREET, LONDON, E.C.)

The rusk is both palatable and nutritious and has the further advantage of being sterilised, since the heat required to cook a rusk is calculated to destroy micro-organisms. The specimens of Dutch rusks which we examined are excellent, the texture is uniform, and while crisp they are not hard. According to the appearance under the microscope the rusk is thoroughly cooked. No less than one-fifth part of the rusk is soluble in cold water and much of the starch is converted into dextrin. These rusks afford an excellent substitute for toast, though perhaps a trifle sweet.

(1) VITOFER PREPARATIONS; (2) INFANT'S MILK FOOD; AND (3) YEAST TABLETS AND POWDER.

(J. STAUFFER AND CO., ENGHEIM, BELGIUM. AGENTS: MATTHAEI AND CO., CULLUM-STREET, LONDON, E.C.)

1. "Vitofer" occurs in brilliant reddish-brown scales which are readily soluble in water, yielding a red solution exhibiting the properties of hæmoglobin. Coagulation occurs when the solution is heated to 70° C. The solution shows the characteristic spectrum of hæmoglobin. According to our analysis vitofer contains 0·6 per cent. of iron in organic association. The moisture amounted to 6·7 per cent. and the total mineral matter to 2·20 per cent. This preparation mixed with chocolate *forms* vitofer chocolates which afford a convenient way of administering the hæmatinic. In the same way vitofer is added to a farinaceous milk food. This food, however, according to our analysis, is deficient in fat, the total amount being *only* 3·30 per cent. Vitofer is prepared from fresh bullock's blood previously deprived of fibrin and fatty matters. It exhibits hæmoglobin in a convenient way and should be of service in conditions of enfeebled nutrition or in which the blood is impoverished. 2. Stauffer's infant's milk food is stated to be prepared from fresh milk and to exhibit a composition identical with that of human milk. We cannot reconcile these statements with the results of our analysis. To begin with, the food is deficient in fat and

---

[1] Cf. Pes, Samivellus; De quadam in hortum ingrediente ad brassicae folium secandum.

besides contains starch and more than half its weight of cane sugar. The total proteids amounted to 14·46 per cent. and the mineral matter to 1·50 per cent. 3 The yeast tablets and powder gave satisfactory evidence of activity. These preparations are intended for internal administration for the treatment of carbuncle and anthrax. Yeast has also been used as a remedy for constipation. These yeast preparations, on account of their purity, are well adapted for medical use.

LIME JUICE AND LIME JUICE CORDIAL.

(L. ROSE AND CO, LIMITED, LEITH; AND 89, WORSHIP STREET, LONDON, E C.)

The lime juice gave the following results on analysis: total solid matter, 8·46 per cent.; mineral matter, 0·40 per cent.; and acidity calculated as citric acid, 7·76 per cent. The preparation was free from salicylic acid but contained sulphurous acid. The cordial gave the following results on analysis: total solid matter, 34·24 per cent.; mineral matter, 0·14 per cent.; sugar, 10·00 per cent.; and acidity calculated as citric acid, 2·94 per cent. The cordial contained both salicylic acid and sulphurous acid for preserving purposes. We have little doubt that both the juice and the cordial are made from the choicest materials procurable and that being so it seems to be a pity that they cannot be preserved without the use of chemical agents.

(1) HÆMABOLOIDS; AND (2) FORMOLYPTOL.

(PALISADE MANUFACTURING CO., NEW YORK; AND ANDRUS AND ANDRUS, 46, HOLBORN VIADUCT, LONDON, E C)

1. "Hæmaboloid" is a liquid preparation which is described as "the combination of the various iron-bearing nucleo-albumins of the vegetable kingdom reinforced by bone marrow extract and beef peptones antiseptically treated with nuclein." It is said to possess considerable therapeutic value in all anæmic conditions and a good deal of clinical evidence is quoted by the makers in support of this view. According to our analysis the preparation contains a considerable amount of iron in an organic form, associated, in fact, with nucleins and phosphorus and peptones. The liquid preparation contains 8·71 per cent. of solid matter, of which 0·6 per cent. consists of iron calculated as ferric oxide. We have also examined a preparation of hæmaboloids containing arsenic and strychnine, the presence of both of which we were able to confirm. 2. Formolyptol is a pleasant and fragrant antiseptic fluid which may be used both internally and externally. It contains glycerine, borax, and formaldehyde, besides the pleasant aromatic and antiseptic bodies pinus pumilio, eucalyptus, myrrh, storax, and benzoin. The preparation is colourless and is a very agreeable form of antiseptic for toilet use as well as for medical and surgical purposes.

ARDATH CABINET CIGARS MINIMUM NICOTINUM

(THE ARDATH TOBACCO CO., 44, WORSHIP STREET, FINSBURY, LONDON, E C.)

We entirely approve of the method under which it is stated the "ardath" cigar is manufactured. The objectionable practice of finishing off the end of a cigar by licking it is strongly discountenanced by these manufacturers according to their statements. The operatives in the factories of this company are compelled, so it is affirmed, to finish the shaping of the cigar by means of a knife only. The selection of the leaf is aimed at producing a "mild" cigar and on trial these cigars proved to be "mild smoking" whilst yielding a pleasant aromatic smoke. We found also that the amount of nicotine does not exceed 2 per cent., which is considerably below that frequently found in Havana cigars.

SCANDINAVIAN STOUT.

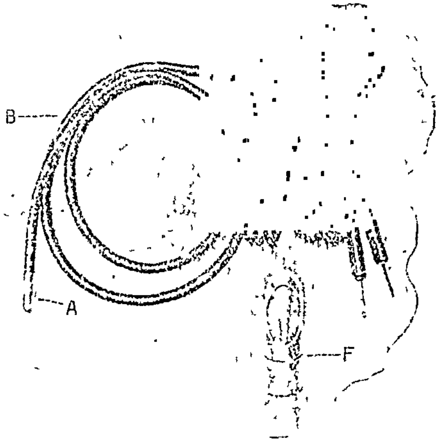
(AGENT: F. DAGGER, 3 AND 4, GREAT WINCHESTER-STREET, LONDON, E C)

This malt liquor gave on analysis the following results: extractives, 8·81 per cent.; mineral matter, 0·36 per cent.; alcohol, by weight 4·62 per cent, by volume 5·78 per cent., equal to proof spirit 10·13 per cent.; volatile acidity reckoned as acetic acid, 0·036 per cent.; and fixed acidity calculated as tartaric acid, 0·25 per cent. This is a good nourishing stout, with an excellent flavour due to malt and hops. The stout was in sound condition, practically free from acidity and from excess of gas. The alcoholic strength is comparatively low, while the nourishing malt extractives are high. These results indicate that the stout is well adapted for invalids' use.

New Inventions.

A NEW GASTRO-DIAPHANE.

As a rapid means of diagnosing dilatation of the stomach and differentiating it from gastroptosis it is probable that the gastro-diaphane would be found of the greatest service in daily practice if it were not so difficult to use. The chief reason for this is the clumsy way in which it is constructed and its comparatively great diameter, the instrument of Einhorn measuring 39 Charrière and having a rigid end of over two inches. It is obviously impossible in most cases to use such an instrument except upon patients who have been accustomed to the passage of the tube. Unfortunately in these it is not necessary as the diagnosis will have been made by other means. It appears to me that if the diaphane is ever to come into daily routine use we must have an instrument which can be readily passed upon a patient who is seen for the first time and who has not previously had a tube introduced into his stomach. It is with the hope of providing such a form of apparatus that I have had the diaphane figured above constructed by Messrs. Lemmon and Co., 19, Hanover-square. It consists essentially of a cystoscope lamp (A), carried on the end of a stomach tube (B) of the same diameter (21 Charrière), connected by means of a switch (D) with the connecting cords (E). At (C) we see the plug connexions between the tube and the switch. The apparatus is so arranged that when the switch is in a position pointing towards the left shoulder of the patient and parallel to it the window of the lamp is directly forwards and in proper position to illuminate the stomach. At (F) the actual size of the lamp and tube is shown. The light emitted appears to be quite equal to that given by the older form of apparatus.



Harley street, W. GEORGE HERSCHELL, M.D. Lond.

the house surgeon “was a good and such a nice man. Miss C., Sirrah and all the rest were in love with him. But the callous young dog went one day and monopolised the heart of one of the visiting doctor's daughters. But he asked all the nurses for a likeness and gave them one of his own; and then went and got married.” We are pleased to be able to state that the nurses, far from resenting this heartless conduct, “bought him a flower-stand from Mappin and Webb's, a silver stand with silver feet, and a glass bowl for the flowers. Sirrah and others filled it with choice flowers and presented it to the doctor who was very pleased with his wedding present.” Nurse Sirrah seems to have been a passionate young woman, for when the new house surgeon was appointed, he was a nice-looking, dark-complexioned man, she “fell in love with him—so that was all right; she was well suited for a lover—in the house and another out of the house—a barber.” Such goings on as these deservedly came to a bad end. The barber “used to furnish her with scent and hair improvers, and bear's grease, and scented pomade, and tooth powder, until she had all her teeth out and then he gave her up.”[1] The house surgeon, however, “stuck to his attentions, found her medicine and a set of teeth, a walking stick, and an umbrella, and then left to marry the late house surgeon's wife's sister.” After this double reverse Nurse Sirrah left Poplar and went to St. Thomas's Hospital where with many regrets we must leave her. Every nurse and every house surgeon should read this work. We have rarely come across any book which gives such a vivid picture of hospital life, not even Mr. Hall Caine's “The Christian.” we cannot forbear from quoting the following dramatic episode as a finish: “So the assistant house surgeon became betrothed to the sister nurse of the children's ward. They married on pain of dismissal. Then the lady superintendent asked the head house surgeon to become betrothed to her. But the doctor replied, expressing his inability to compete, saying his engagements were so many and some so urgent that he could not possibly grasp such an enormous link to unite in matrimony, particularly with one who was a widow and herself a lady of rank.”

they live and whose suggestions will be realised, if at all, only by subsequent generations, and those who are from the first visionary and unpractical. If memory does not deceive us the meetings of the deceased association were largely occupied in listening to counsels of perfection not destined to be realised in this imperfect world, and hence, although the reforms proposed were usually of a kind which could only be carried into effect by the aid of legislation, most prudent legislators were accustomed to look askance at them. There were, of course, some which involved no special legal requirements; and we have a distinct recollection of one much-applauded paper in which it was suggested as a remedy for most of the domestic evils afflicting the working classes that their girl children should be taught, even from infancy, to modulate their voices to dulcet harmonies, in order that it might be practically impossible for them, when adult age was reached, to excite the anger of brutal husbands by shrill-toned scolding or vituperation. Not only was the soft answer to turn away marital wrath; but its very softness was to be enhanced and emphasised by the music of the voice in which it was delivered. The nature of the precise steps by which the indicated reform was to be brought into operation was not, so far as we recollect, very clearly indicated by the author.

Among the leading spirits of the new movement a prominent place is held by that accomplished statistician and student of heredity Mr. FRANCIS GALTON, F.R.S., and we have been favoured with a preliminary proof of a paper on "Eugenics," its definition, scope, and aims, which he is to read before the new society on Monday next. The definition is necessary because—although Mr. GALTON is not using the word for the first time and although his invention and earlier use of it has secured for it a place in the English language, so far as that distinction can be afforded by the great Oxford Dictionary—it still can hardly be said to convey, as a matter of etymology, all that its author or inventor seeks to place upon its shoulders. Mr. GALTON does not realise with sufficient clearness that the prefix "*Eu*," even if we follow him in regarding it as the equivalent of "*good*," leaves the definition of good entirely doubtful; nor does he seem to be aware that the kindred compound, "*Eugenesis*," found its way into biological jargon many years ago as a coinage intended to denote mere fertility of parents without any reference to the quality of the offspring. In the latter sense the old Poor-law, under which every labourer was encouraged to marry early, and was paid an increased allowance from the rates on the birth of each successive infant, was probably the greatest and most effective promoter of eugenesis that the world has witnessed, but we greatly doubt whether Mr. GALTON would desire to restore it as an aid to the cultivation of eugenics. We have no wish to quarrel with a word, but if COBBETT had any justification for his famous requirement that an English sentence should be as clear as a pebbled brook, we may surely urge as an essential condition that the words of which the sentence is composed should convey the same ideas to all who see or hear them, and should be in no need of tedious interpretation either by footnotes or in the text. The "science of eugenics," we are told, "deals with all influences that improve the inborn qualities of a race; also with those that develop them to the utmost advantage." If we accept the common definition of "science" and employ the word to mean methodically arranged or digested knowledge, we must humbly express a doubt whether any science of eugenics is at present in existence or whether there is any probability of its being constituted at an early date. All that has so far been presented to us is a series of suggestions that this and that obscure problem might perhaps be solved if a proper amount of care and study were bestowed upon the collection and marshalling of facts calculated to lead to the solution. In the later portions of his paper, from which we hesitate to quote because what we have received is a proof open to revision, Mr. GALTON escapes from the generalities of the commencement and describes it as the aim of "eugenics" to make the more useful classes of the community contribute more than their rateable proportion to the next generation. In other words, he looks to the new or projected science as an agency which will promote the physical and intellectual development of the human race. We say human race advisedly, because it is inconceivable that the "more useful classes," whichever they may be, could be improved in any sensible manner except by means which to some extent would reach and influence the less useful classes also.

So far as our own outlook extends we can only discover one department of science by which the human race is in the least likely to be improved in the manner indicated, and that department is physiology, applied in the first place to nutrition and in the second place to education. We want physiologists to tell us how the young human organism should be reared and fed in order to develop to the utmost the latent possibilities of each individual, and to tell us also how the cells of the immature brain may be guided towards effective growth in this or that direction. Neither of these problems can be insoluble, but no definite attempt at solving either of them has so far fallen under our observation. Mr. GALTON refers to his favourite subject of heredity, but we doubt whether studies of real or apparent hereditary influence will be helpful in the present state of knowledge, or we should perhaps say of ignorance, about the essential conditions of physical or of intellectual activity. We do not gather figs from thistles, and it is obvious to common observation that offspring seldom rise greatly above the level of their parents. But, on the other hand, we see such wide dissimilarities between the offspring of the same parents that we must fall back upon vague conjectures about atavism before we can find any words which appear to offer an explanation of the familiar facts. Even twins, while sometimes marvellously alike, are in other instances markedly different from each other in formation, in character, and in capacity. The feeding of the children of the nation is at present regulated partly by tradition supposed to be based upon experience and partly by the interested falsehoods of the common advertiser. The education of the same children is regulated by the ideas of the preacher, the schoolmaster, and the county councillor. We greatly fear that the new society is likely to fall into the hands of men who will talk grave nonsense about what they call "psychology" and who will neither know nor seek to know anything of the growth or the recuperation of brain tissue. The time has surely come when the problems of immature existence should be boldly grappled with by the physiologist, and when the discoveries of the physiologist should be prepared for public assimilation by the physician.

◆

Horrors without Foundation.

The recovery of the ill-fated submarine A 1 a fortnight ago, the coroners' inquest upon her gallant officers and crew, and the payment of the last honours to their remains revived the national sorrow as well as the grief of those mourning for relatives lost in her. But the pain now felt should be less terrible than the uncertainty and fear which must have beset them owing to rumours which before were current as to the possibility of those on board having died a lingering and painful death. These questions have been set at rest—men and officers died at their posts and if they could make no struggle to save themselves were at least spared the agony of making it in vain, but we are entitled to ask what justification there was for the horrible surmises which appeared in the daily press. The most detailed and circumstantial form which the rumours referred to assumed was to be found in the columns of the *Daily News* of April 11th and it is against the needless publication of horrors of this kind without the closest examination as to their truth and the most careful sifting of the facts alleged that we protest on behalf of the public at large and on behalf of those more intimately connected with the dead. The matter to which we refer filled about half a column of the newspaper. It was headed, "Truth about A 1," and the same line formed a conspicuous item in the contents bill. The story told was based upon an alleged examination of the interior of the submerged boat by the divers and was to the effect that of 11 men and officers one was missing. The details were complete, even the name of the missing man was given, with the suggestion that he had been released through a torpedo-tube in order to endeavour to accelerate the rescue of his comrades confined still alive in the submarine. A well-known diver employed was named as the authority for this statement and also for one to the effect that a message written on a sheet of paper torn from a note-book had been left by the crew, but, it was added, the contents had not yet been made known. Other details included a story that the submarine had been raised and towed to Bemridge Ledge off the Isle of Wight, presumably as a preliminary to the ultimate removal to the dock which, as everybody knew, was to be its ultimate destination. Below this tale came two notes, the one relating to the rough weather which had rendered all progress impossible and the other recording a denial by Sir John Fisher of the report that the vessel had been raised to the surface and the bodies examined. This denial was qualified as "official" and to the whole was appended an editorial note "We have been unable to communicate with our correspondent whose statement we give with reserve.—Ed. D.N." To what extent the expression "with reserve" applies to a story headed "Truth About A 1" we leave to our readers to decide, only adding that it was followed in conspicuous type at the head of the column by the lines "Terrible Spectacle," "Doomed Crew's Message," "One Body Missing"; "From our own Correspondent, Portsmouth." The mental picture of suffering and death suggested by these words and by the account to which they called attention we need not dwell upon. The story was one which in the interest of the living relatives of the dead, as well as of the wider public which sympathises so deeply with them, might well have been suppressed even had it been true in every particular.

The recording of horrors wholly or in part without foundation is, however, not a rare occurrence in the cheaper newspapers which no doubt find that their readers like something which will "make their flesh creep." It is, however, discreditable to the newspaper when it occurs and it is a practice which adds to the bulk of demoralising literature daily laid before the classes least fitted by education and temperament to withstand its subtle influences. Tales of death and of crime are not wholesome reading for the weak-nerved and morbid minded and if it is necessary that some publicity should be afforded to them it is highly undesirable that fictitious additions should be allowed to increase the attraction which they present to depraved intelligences. As an instance may be cited a story told in the *Star* of Dec. 31st, 1903, headed "Murder!" "Woman gagged and killed off Tottenham Court-road." A young woman had been found dead in her bedroom with her throat cut, and difficulty afterwards arose in determining whether she had been murdered or had committed suicide with the aid of a piece of glass. The account given in the issue of the *Star* referred to began with the words, "Thus far all that can be stated with certainty is this," and after other points had been touched upon went on to say, "The police were eventually called in only to find the woman's nude body lying on the bed with her throat cut in the most terrible fashion. She had been gagged and blindfolded and her hands bound together across her breast." From the evidence at the inquest it appeared that the woman's throat was cut, but that when the police broke in only her head and shoulders were uncovered. Her nudity, her gagged, blindfolded, and bound condition, all the "horrible details" in short, had no foundation in fact; a statement that she had been robbed and that her valuables were missing was also apparently untrue. With the suicide or the accidental death, however, which figures in the newspapers as a "Mysterious Crime" until the sworn evidence at the inquest throws the light of truth upon it we are all familiar. Unfortunately the "mysterious crime" is a more exciting and attractive topic for the morbid-minded section of the public than the death of the mentally deranged by his own hands or the tragic result of a commonplace mishap. The anxiety which at times is felt with regard to public personages and the issue of public events affords an opportunity for the circulation of many untrue stories and at the same time adds to the distressing effect which these may produce. The horror excited by a statement published in the *Daily Mail* as to the fate of those who were known to be undergoing siege in the embassies at Peking will be recalled as an instance of "news" of this class. The present war between Russia and Japan has afforded, and will continue to afford, abundant opportunity for the publication of the horrifying but wholly or partly untrue reports of disaster and massacre, an opportunity which we venture to hope will be used as sparingly as possible in this country.

The complete elimination of untruth and inaccuracy from all matter published is, of course, impossible. News has to be brought out promptly if it is to remain news at all. When, however, it relates to topics which if true can only shock and distress, when a suspicion of improbability attaches to it and all external circumstance and trustworthy evidence which might even indirectly corroborate are absent, it may surely be omitted without the newspaper losing its name for enterprise and general attractiveness. The value of a reputation for honourable reticence and for purveying that which can be relied upon as true is also a matter for the consideration of those interested in a journal's material prosperity.

The Office of Coroner.

A PARAGRAPH in our New York correspondent's letter on p. 1314 of THE LANCET of May 7th announced that after a struggle lasting many years the medical profession of New York city has succeeded in getting a Bill through the State Legislature to abolish the office of coroner. It may seem to some a little anomalous that there should exist in so democratic a community an office associated with obsolete functions of extreme antiquity and deriving its name from services rendered directly to the Crown, but the title of coroner has long been dissociated from the duty of recording the "placita coronæ" or "pleas of the Crown" and of watching those sources of Crown revenue which might arise out of the punishment of crime. In days when *felo de se* and other felonies produced forfeiture of goods and when an accidental death might result in the chattel which caused it being handed over to the Crown or to the Crown's grantee as a "deodand," the "crowner" was a knight of high standing in his county and the proper performance of his duties was a matter of direct interest to his sovereign. In New York, however, as in England, the main duty of the modern coroner has been to hold inquiries of one description only and of a kind which makes it highly desirable in the public interest that they should be intrusted to medical men. There are no doubt many differences between the coroner in New York and the synonymous judicial officer on this side of the Atlantic. Our correspondent's letter showed this where it informed us that the change which he announced had been delayed because "the four coroners of the city have hitherto been a power in politics that defeated year after year the united efforts of all our medical organisations," a condition which those familiar only with British political methods and with the position occupied by British officials may find difficult to grasp. The innovation, however, which our correspondent briefly described showed that the efficient investigation of the cause of death in all cases has been the object sought by the medical profession in New York and that is the end to which criticism of the coroner's functions has always been addressed in THE LANCET ever since the late THOMAS WAKLEY first applied himself to the subject and personally filled the office in question. In New York the Health Department is to institute a "Bureau of Medical Examiners," presided over by a pathologist and composed of medical men, with the duty of determining the cause of death. The district attorney is to take charge of the case when an element of crime enters into it, and the existing coroners during the residue of their terms of office are to preside at inquests as before. The organisation of the new system in detail and its practical working should be watched with interest in the country which originated and developed the system thus superseded. Deaths are not inquired into by coroners in Scotland, but in England and in Ireland, under different Acts of Parliament and in various circumstances, this important duty is intrusted to the coroner in a limited number of cases. He is not expected and is not empowered to afford to the public more than a moderate degree of protection. His inquests do not even cover all the ground left vacant by the absence of the medical attendant's death certificate. He has power to hold them only "where he is informed that the dead body of a person is lying within his jurisdiction and there is reasonable cause to suspect that such person has died either a violent or an unnatural death, or has died a sudden death of which the cause is unknown, or that such person has died in prison," or where an inquest is required under any Act of Parliament. In order that he may be able to determine whether an inquest should be held or not subject to the limitations thus imposed, as well as in order that he may conduct it efficiently, it is clearly of the utmost importance that the coroner should be a medical man, and of recent years, particularly in large towns, medical men as a rule have been chosen for these appointments, but even thus it cannot be said that the cause of death is established as certainly or as universally as it should be in a highly civilised community such as ours. It will be interesting to observe the nature and extent of the change effected in New York by the "Bureau of Medical Examiners" of the State Health Department. No doubt the bureau will enter upon an extremely difficult task but its experiment, even if not at first completely successful, will afford a valuable guide to others.

Annotations.

"Ne quid nimis."

METROPOLITAN STREET AMBULANCE ASSOCIATION.

THE general purposes committee of the London County Council received on May 9th at the offices of the London County Council, Spring-gardens, a deputation from the Metropolitan Street Ambulance Association. The deputation comprised amongst its number Mr. Reginald Harrison, the President of the association, Sir William S. Church, President of the Royal College of Physicians of London, Sir Alfred Cooper, Vice-President of the Royal College of Surgeons of England, Sir Thomas Barlow, Mr. A. A. Bowlby, Mr. Raymond Johnson, Dr. H. D. Rolleston, Mr. C. S. Wallace, Dr. R. Dudfield, and Dr. Arthur W. James, the honorary secretary, who originated the association. With the deputation there were also Lieutenant-Colonel Sir R. Temple and Colonel Sir H. C. Perrott, representing the St. John Ambulance Association. This influential deputation was introduced by Sir William J. Collins to Mr. Thomas McKinnon Wood, the chairman of the general purposes committee of the London County Council. Mr. Harrison, as president of the association, stated briefly the reasons why the deputation approached the London County Council in the hope of inducing that authority to graft upon the Fire Brigade an efficient ambulance service. Sir William Church, who next spoke, drew especial attention to the great saving of cost that would ensue if the advantageous method of combining the Fire Brigade and ambulance services was adopted. It was stated that the Poplar Hospital was estimated to receive four cases of accident or sudden illness every hour day and night throughout the year. The representatives of the St. John Ambulance Association also stated how anxious their association was to help the proposed plan in every way. A large portion of the time was occupied in answering the many questions asked by the members of the general purposes committee; these were mostly responded to by Dr. James who explained that the proposed ambulance service would not put more work on the Fire Brigade as at present constituted. It was estimated that every year 15,000 casualties had to be removed to hospitals and the association suggested that a sufficient number of men, horses, and ambulances should be added to the Fire Brigade to deal efficiently with the task. It would appear that out of the 90 fire stations only 30 would have to be furnished with ambulances. Dealing with the question as to whether calls for ambulances would not interfere with the alarms for fire Dr. James explained how such calls nowadays were carried out by means of telephones and in this way no inconvenience would arise as might possibly have been the case if the old plan of simply using a bell were still in use. Some confusion seemed to exist as to what should be expected from the police but Dr. James was able to clear up the difficulty entirely by pointing out that the police would help in the ambulance service in exactly the same way as they helped in cases of fire. The council has appointed a subcommittee to consider the question.

THE INQUEST UPON MRS. PIERCY.

A SAD occurrence which took place at the West London Hospital recently has been made the subject, consequent on the publicity of the proceedings before the coroner, of some unjust reflections upon the institution in question. We need not enter into the details of the story as they have been brought to the attention of all the medical profession, but the gist is as follows. A patient was operated upon for a ruptured Fallopian tube in circumstances of great hurry, the need for the hurry being her absolutely desperate condition. The operation proved only partially successful and a recurrence of symptoms led to the reopening of the abdomen. It was then discovered that a small pair of forceps had been left in the abdomen after the first operation. The patient died and the coroner's jury, having heard the evidence of the surgeon who performed the first operation, of his house surgeon who assisted him, and of the nursing sister in charge of the theatre, brought in the following verdict: "Death from misadventure due to peritonitis following an operation, accelerated by the presence of the forceps," adding as a rider, "we consider the system at the hospital is largely at fault and suggest that in future all instruments should be numbered and counted before and after each operation." The operating surgeon, a man of many years' experience, was able to bring unimpeachable testimony to his scrupulous care as an operator, while the possibility of such a deplorable oversight occurring despite rigorous precaution was also proved. The jury quite appreciated these points, but they evidently considered that at the West London Hospital the procedure in regard to such operations was not attended with due care. The evidence of the theatre sister was to the effect that the sponges were counted as a matter of routine both before and after the operation but that the instruments were only counted before the operation, and this statement puzzled them, as, indeed, it puzzled us. An examination, however, of all the circumstances puts the matter in a much more favourable light for the hospital. We have now received statements from the two nursing sisters who have been in charge practically of the operating theatre at the West London Hospital for the last six years and it is clear that the "system" which has been blamed does not exist. The independent statements of these two sisters show that there is no defect in the system of checking instruments at the hospital, although, to the profound regret of everyone concerned, the routine at the West London Hospital—the counting and checking which prevail, of course, everywhere else—was not observed on this occasion. Each sister says that upon taking charge of the operating theatre she was enjoined to count the instruments, sponges, and swabs before and after every operation and to hold herself responsible for having done so. On the lamentable occasion in question the nursing sister, following instructions, detected that a sponge was missing and it was found in the abdomen, but it does not seem to have occurred to anyone concerned that an instrument might also be concealed in a similar manner. A reason for this oversight has been communicated to us by the senior surgeon of the hospital who writes:—

> Changes in methods occur in a progressive art like surgery and the following most important change must be remembered. Whereas years ago it was the custom to stop hæmorrhage inside the abdomen by applying small artery forceps to numerous points and afterwards tying those points one by one, many surgeons have almost entirely discarded this plan. I do not think that I myself have put out of sight a single small pair of forceps in the last 300 abdominal operations performed by me. I remember well the preoccupation of mind it caused me on the last occasion when I did such a thing. So it happens that while within the last few months I have on various occasions reminded the sister about counting swabs placed in the abdomen, I have never had to ask her about counting the instruments. As no instruments were put out of sight, it was unnecessary to do so. Some, if not all, of my colleagues have, I know, acted much in the same way. Thus, the house surgeon, the sister, and all concerned have had constantly held up before their eyes the importance of counting the sponges, while actual recent experience has tended to minimise the ancient and necessary rule that instruments should be counted too.

We think that the view taken by the senior surgeon is almost certainly right, and confirmation is given to it by the fact that the present theatre sister, for whose care and conscientiousness we are in a position to vouch, had only returned to the position after an absence from work in the operating theatre of over six years. If we further bear in mind that this unfortunate oversight took place in connexion with a case of acute hæmorrhage of the most dangerous description, and if we appreciate that the operations of surgery must sometimes be done under conditions of emergency and haste which resemble those found in the operations of war, it will be recognised by every fair-minded person that even the most careful surgeon, aided by the most scrupulous assistants, is liable to be visited by a similar calamity. Just as it is impossible to make any delicate mechanical contrivance absolutely "fool-proof," so it is impossible to invent any system of counting instruments and sponges which will entirely do away with human fallibility. We have the deepest sympathy with the husband of the unfortunate woman, and are in no way attempting to lessen the catastrophe when we say that it is quite likely that the overlooked forceps had nothing to do with her death.

DISTRIBUTION OF PLAGUE.

LORD MILNER in a telegram received at the Colonial Office on May 2nd states that since April 23rd 14 fresh cases of plague have been notified in the Transvaal, 11 being in coloured persons and 3 in white persons. Out of the suspected cases 32 have been found to be not suffering from plague, making the total number of suspected and proved cases to be 142—viz., coloured persons 123 and whites 19. Since April 23rd 5 deaths have been reported, all being of coloured persons. For the week ending May 7th the total number of fresh cases reported since April 30th is 11, 6 being white persons and 5 coloured; 19 cases have been found not to be plague, making the present total of suspected and proved cases 134, 22 whites and 112 coloured. The number of deaths for the week is 4, 1 of a white and 3 of coloured patients. In Cape Colony for the week ending April 16th only 1 case of plague was reported—namely, a coloured male at Port Elizabeth. Plague-infected rodents were also found in the town. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on May 6th states that for the week ending May 5th there was 1 case of plague which proved fatal.

DOES SYPHONAGE OCCUR IN THE LARGE INTESTINE?

A LIVELY controversy has been going on lately in our columns as to the way in which the colon propels its contents into the rectum preparatory to their evacuation. Dr. R. W. Leftwich is an advocate of a novel view, for he seeks to explain this action of the colon on purely hydrostatic principles. He considers that hydrostatic pressure is brought to bear on the large bowel by the small intestine at the ileo-cæcal orifice and that the colon, in man at all events, acts after the manner of a syphon of which the descending colon and its continuation form the longer limb. In a small volume in which he has published the results of his speculations and experiments Dr. Leftwich advocates the avoidance of the recumbent position in strictures of the colon, points out that the proper position after the administration of an enema is the erect one, conjectures that intussusceptions are the results of cæcal vacua, and states that in typhoid fever the patient should be made to sit up, during the first ten days at all events, for stated intervals. He certainly has the courage of his opinions. His opponent, Dr. A. Keith, has with persistence asserted that this view of the purely hydrostatic action of the colon in emptying itself is erroneous. Dr. Keith's chief reasons for dissenting from the theories of Dr. Leftwich are the known consistence of the contents which is not such as to favour syphonage; the impossibility under normal conditions of maintaining a rigid and at the same time freely pervious colon; the great development of the muscular coats of this part of the bowel; and, lastly, the actual demonstration of peristaltic movements in it. Dr. Leftwich, on the other hand, doubts the power of the human colon to propel its contents against gravity and infers that the rigidity of the tube is sufficiently provided for by tonic contraction of its longitudinal bands and the support yielded by the doubling in of the ridges between the saccules. He holds that the failure of saline purges if the patient retires to bed after taking them, the occurrence of morning diarrhœa in some conditions, and the normal morning evacuation all support his contention of syphonage as the active agent in causing the onward passage of the contents of the colon. We think that Dr. Keith has advanced cogent reasons for doubting the presence of such a mechanism as that which Dr. Leftwich invokes and our scepticism is strengthened when we turn to a description of the mechanism as given by Dr. Leftwich in his own book, for at one stage he postulates the following condition of affairs: an inverted rigid U-tube (the colon) with a vacuum at the cæcal end and a fæcal column suspended between the cæcum and the rectum, the end which lies in the descending column in some mysterious way supporting the end which lies in the ascending colon. Since the publication of Dr. Keith's last letter we have received a further communication from Dr. Leftwich in which he still maintains his original position. The discussion is of use in that it draws attention to the possible normal condition of the colon during life. This portion of the bowel is probably in a condition of slight tonic rigidity and in its empty state has practically no lumen. Considerable lengths of the colon may occasionally be seen in a firmly contracted condition during abdominal operations on man and a similar appearance is not infrequently met with after death, especially in the descending, iliac and pelvic sections of the bowel. This is quite comparable with the condition held to obtain in the living empty stomach. We cannot see, however, that any advantage will accrue by further discussion of the matter in our columns.

HENRY MORTON STANLEY.

BY the death of Sir Henry Morton Stanley, which occurred on May 10th from pleurisy and pneumonia, the country has lost a typical British explorer. Born in very humble surroundings in Denbighshire, he raised himself, partly by his own innate talent and partly owing to the kindness of a merchant named Stanley whose name he adopted, to a position on the staff of the *New York Herald*. The chief incident in his career of interest to our own profession was that he was the discoverer of Livingstone who had for years disappeared within the heart of what was then literally "the Dark Continent." The historic meeting between Livingstone and Stanley took place at Ujiji in 1871. Two years afterwards Livingstone died alone except for the presence of one faithful servant at Ilala and his body being brought home Stanley was one of the pall-bearers when it was laid to rest in Westminster Abbey. In 1874 Stanley again left England for Africa to undertake an exploring expedition under the auspices of the *Daily Telegraph* and the *New York Herald* and explored a great deal of the Congo territory. Of the foundation of the Independent State and the expedition for the relief of Emin Pasha we have no space to give details, but it may justly be said that Stanley's explorations put the coping-stone to the building raised with such toil and indomitable energy by Denham, Barth, Burton, Speke, Grant, and Baker, to mention only a few of those who have devoted their lives to solving the problems of Africa.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE twenty-second anniversary dinner of the West London Medico-Chirurgical Society was held on May 4th at the Empire Hall of the Trocadéro Restaurant, Piccadilly-circus, London, W., Dr. Seymour Taylor, the president, being in the chair. After the usual loyal toasts had been honoured Colonel T. H. Hendley, I.M.S., in responding to the toast of "The Imperial Forces," which was proposed by Mr. C. B. B. Keetley, referred to the serious misgivings caused by the determination of the authorities to omit from the Army Council the head of the Army Medical Service. If the Medical Service of the army was expected to show successful results in war there should be full preparation in time of peace and that could only be secured by continuity of administration and by full representation. The Indian Medical Service had no official representation on the supreme or provincial legislative councils. However, the good sense and courtesy of lieutenant-governors and other officials minimised this want of representation in the Indian Medical Service. Few realised perhaps in how many ways the men in the Indian Medical Service were in touch with the history and daily work of the empire. Boughton and Hamilton were among the founders of the Indian Empire and Holwell, the hero of the Black Hole of Calcutta, was for a time Acting Governor of Bengal. Continuing, Colonel Hendley pointed out that two officers who had recently served under him were now on special service, one Colonel L. A. Waddell, I.M.S., medical officer and antiquary with the expedition in Tibet, and the other, Major R. Bird, I.M.S., in Cabul on a mission to the Ameer. Colonel Hendley concluded an interesting speech by affirming that such variety of work and responsibility demanded unusually wide powers of control and representation. Mr. H. Percy Dunn and Mr. W. McAdam Eccles were each presented with a silver bowl for the services which they had rendered in editing the journal of the society. The toast of "The Kindred Societies and Guests" was intrusted to Mr. Stephen Paget and was replied to by Dr. F. de Havilland Hall and Dr. C. Theodore Williams. Mr. F. Swinford Edwards proposed "The President and the Society" which was acknowledged by Dr. Seymour Taylor. In the course of the evening those present were entertained with songs and recitations by Dr. J. Blumfeld and Mr. Walter Ivimey, assisted by others.

STUDYING FOR THE BAR.

MEDICAL men desirous of becoming qualified as barristers-at-law not infrequently apply to us in quest of information as to the proper course to take. Omitting details, the following is a rough outline of the necessary procedure. Three important conditions have to be complied with—namely, (1) the student must join one of the Inns of Court; (2) a certain number of terms must be kept; and (3) certain examinations must be passed. Finally, certain fees amounting to about £150 must be paid. There are four Inns of Court, the Inner Temple, the Middle Temple, Lincoln's Inn, and Gray's Inn, but it matters little to the non-practising barrister which he joins. Before joining an inn, the student must produce evidence of education sufficient to satisfy the Council of Legal Education. This is easily done by means of a certificate obtained from the inn which he proposes to join, showing that he has passed a public examination at one of the universities, such as Responsions at Oxford, the "Little-go" at Cambridge, the matriculation examination of the University of London, or such other examinations of like nature as may be approved by the Council. Those who are unable to produce evidence of the first two requirements may pass an entrance examination instituted by the Council. Having satisfied himself as to his eligibility the student should obtain a form of application for admission to his proposed inn, not omitting to send a guinea at the same time. This application when returned must be accompanied by two separate certificates of respectability and general fitness for membership of an inn signed by barristers of at least five years' standing. With regard to fees on admission, it is usual at all the inns for the student to pay a deposit of £50 towards his commons, the balance over (at the time of call) going towards his call fees. At certain inns caution money to the extent of £100 is required from non-university men. The other entrance fees at all inns amount to about £40. This sum includes £25 for Government stamp and a sum of £5 5*s.* to admit to all law lectures. With regard to the keeping of terms 12 terms spread over three years are required. In order to keep a term six dinners (three for members of any university in Great Britain and Ireland) must be attended. The subjects of the examination are (*a*) Roman law; (*b*) constitutional law and legal history; (*c*) the law of evidence and procedure and criminal law; and (*d*) the law of real and personal property, the law of contracts and torts and the principles of equity. Parts (*a*), (*b*), and (*c*) can be taken separately and at any of the four annual examinations after joining an inn but (*d*) cannot be taken until eight terms have been kept, when the three other divisions can be taken with it if so desired. Those who have already passed certain examinations in Roman law can claim exemption from (*a*), but no other subject is excused by reason of the results of examinations passed elsewhere. The standard required for a pass has been considerably raised during the last few years; therefore steady reading on the part of the candidate is necessitated. Those who have the leisure should attend the lectures, delivered by the readers and assistant readers, which deal with the special subjects forming the basis of the examination questions. It should be noted that those who obtain a first class in division (*d*), generally known as the final examination, can be called in their tenth term. Lastly, the fees payable before call amount to about £100, which sum includes £50 for a Government stamp, dues for 12 terms' dinners, and an amount which compounds for all future dues. Those of our readers who desire more particulars can obtain all the necessary information from the treasurer's office at any of the Inns of Court.

MENINGITIS IN TYPHOID FEVER.

THE modern method of lumbar puncture enables meningitis to be diagnosed under conditions in which this was formerly impossible and reveals its existence in mild forms in many infectious diseases. We have recently called attention to this fact in the case of mumps.[1] At the meeting of the Société Médicale des Hôpitaux of Paris on April 15th M. Ch. Achard and M. G. Paisseau showed that the same holds true in typhoid fever and other infections. The views held with regard to meningitis in infectious diseases have passed through several phases. For a long time cases presenting meningeal symptoms were scarcely considered instances of meningitis if they were not fatal and were termed by French writers "*méningisme.*" Then it was shown that by lumbar puncture recovery was possible in meningitis and even in suppurative meningitis. Later, cytoscopy showed the existence of slight meningitis with purely histological lesions in cases formerly termed "*méningisme.*" At the same time it was found that "histological meningitis" might exist without any meningeal symptoms. M. Achard and M. Paisseau reported the following case. A lad, aged 18 years, entered hospital on Oct. 23rd, 1903, complaining of severe headache and backache which had obliged him to leave work. He was in good health until the beginning of October, when he began to suffer from malaise, lassitude, and want of appetite. For some days before admission he had had headache and repeated rigors. Nevertheless, he worked until the day before admission. On the 24th there was rigidity of the neck with limitation of flexion and rotation of the head, which were painful. Kernig's sign was well marked. During the previous night there had been delirium. The patient was constipated and several times vomited glairy matter. There was a little albumin in the urine and the diazo reaction was distinct. The temperature was 103·1° F. in the morning and 104·3° in the evening. Lumbar puncture yielded clear fluid which was found on centrifugalisation to contain an abundance of lymphocytes. Culture media were inoculated with negative result. The puncture was followed by marked relief of the meningeal symptoms. On the 26th rose spots appeared on the abdomen and Widal's reaction was obtained. On the 27th puncture of the spleen was performed and yielded cultures of the typhoid bacillus. On the following days the temperature was lower and Kernig's sign and the rigidity of the neck disappeared and convalescence followed. In this case the meningeal symptoms were sufficiently marked to establish a strong presumption of meningitis. When the symptoms are ill marked a similar "meningeal lymphocytic reaction" may be obtained. The fact that the fluid was sterile shows that the meningitis was due to the action of toxins. In the same way cases occur in which there are meningeal symptoms without the cerebro-spinal fluid showing any signs of meningeal reaction. The explanation of such cases is that the symptoms of meningitis are "borrowed"—i.e., are not due to the meningeal lesion but to vascular or inflammatory troubles of the subjacent nervous tissue. Hence it is conceivable that the nervous elements may be altered without the serous membrane being inflamed. Further, another explanation is possible: the meningitis may be limited to the cerebral membranes and cause no change in the fluid extracted by lumbar puncture. Several examples of this have been published. At the same meeting of the Society M. Netter read an important paper on a similar subject. Since 1898 he has systematically looked for Kernig's sign and found it one of the easiest and most certain means of recognising meningeal irritation. He has frequently found it in two diseases—typhoid fever and pneumonia. Out of 313 cases of typhoid fever he found it in 44. Some of these cases showed other signs of meningitis—rigidity of the neck and trunk, pains in the head and limbs, contractures, convulsions, and paralysis of limbs. Cases of typhoid fever in which Kernig's sign occurs are unusually serious. M. Netter has found that the mortality and the liability to relapses are about thrice as great as in cases in which the sign is absent. When Kernig's sign is present the nature of the fluid obtained by lumbar puncture varies as described above. On several occasions M. Netter has isolated microbes from fluid obtained by lumbar puncture in typhoid fever, not always the typhoid bacillus, but sometimes the pneumococcus, the staphylococcus, and the streptococcus. Even if the fluid is apparently normal meningitis is not negatived.

---

[1] THE LANCET, May 7th, 1904, p. 1297.

THE RUSSIAN MEDICAL COUNCIL.

THE Russian Medical Council was confirmed by Imperial Decree on March 22nd last in its premier position as the highest medico-scientific institution in the empire in the matter of advising as to questions affecting the public health, medical practice, and medico-legal inquiries. The new charter is composed of 23 articles which, *inter alia*, charge the Council with the preparation of the Pharmacopœia, taxing and classifying medicines and regulating their sale, and controlling the preparation and sale of new medicines and the importation of such from abroad; its duties will also include the censorship of medical works. The Council will deal with medical practice in Russia by holders of foreign diplomas, certain categories of whom will only be admitted to practise after the customary examination in the Imperial Military Medical Academy or in one of the universities, resulting in the granting of a degree; others of a certain reputation may be admitted after an oral examination before the Council; and, finally, those who may have made a name in the professional world by their works or by the occupation of professors' chairs, or the like may be accepted without any examination at all by a simple decree of the Council confirmed by the Minister of the Interior. Article IX. provides that the Council shall consist of a president holding the degree of a doctor of medicine, *ex-officio* members and consultative members, and a professional secretary. The *ex-officio* members are the Chief Medical Inspector of Public Health, the Chief Military Medical Inspector, the Chief Medical Inspector of the Fleet, two Court Medical Inspectors, a Director of the Imperial Institute of Experimental Medicine, a president of one of the departments of the Orthodox Religion, the Ministers of Finance, Public Education, Agriculture and Government Property, Justice, Public Highways, and Foreign Affairs; the chief of the Commercial Navigation and Ports Department, the President of the Veterinary Committee and the Chief of the Veterinary Executive, all to be appointed by decree of the Senate. Consultative members are to be chosen from scientific circles by a two-thirds majority of a minimum of half the total membership.

INVALID CHILDREN'S AID ASSOCIATION.

A CONFERENCE has been arranged by the Invalid Children's Aid Association, to be held by the kind permission of the Lord Mayor at the Guildhall on June 7th and 8th, the object of which is to bring into communication those working in aid of crippled and invalid children, to make known the various needs of this class and the agencies available for supplying them, and to consider the education of crippled and invalid children and the means of fitting them for future occupation and independence. The relation of this work to the Poor-law and to charity organisation will also be discussed, as well as the possibility of preventive measures. The Lord Mayor will preside at the opening meeting and at the four sessions of the conference the chair will be taken by the Earl of Aberdeen, Sir William Broadbent, the Duchess of Sutherland, and Lord Stanley of Alderley respectively. It is hoped that the social, economic, and ethical importance of the subjects to be discussed will render the conference both attractive and useful and that there will be a large attendance of active workers and of those interested in its objects. Programmes, tickets, and other information can be obtained from the Secretary, Invalid Children's Aid Association, 8, Henrietta-street, Covent-garden, London, W.C.

CHONDRODYSTROPHIA FŒTALIS.

AN important paper dealing with this comparatively rare affection, which has often hitherto been mistaken for rickets and miscalled "fœtal rickets," is published by Dr. P. W. Nathan of New York in the *American Journal of the Medical Sciences* for April. Most children affected with chondrodystrophia fœtalis are either born prematurely or born dead at full term. The affection is, therefore a serious disease with a high mortality. Those infants who are born alive, says Dr. Nathan, are usually very weak and for some time life is precarious. In 1836 Busch gave a very accurate description of a case which he then called "congenital rickets," noting all the salient features—viz., the very large head with prognathous jaws and flattened nose, the short and deformed limbs, the large epiphyses of the long bones, the "rosary" on the ribs, the deformed pelvis, and general obesity. Müller (1860) showed that this was really a disease of the fœtal cartilage preceding the period of bone formation and that it had nothing in connexion with rickets. The most important advance in our knowledge of chondrodystrophia fœtalis was due to Kaufmann (1892) who, having had the opportunity of studying 13 cases, was enabled to clear up many points in its pathology. Dr. Nathan's observations were made on five cases of chondrodystrophia fœtalis and the following results were ascertained. The head was very large and appeared disproportionate in contrast to the defective length of the fœtus as a whole. Its circumference was from 18 to 20½ inches. The arms were short and did not reach the waist-line and the legs were so short and bent that the middle point of the body instead of coinciding with the navel was nearer to the ensiform cartilage. The epiphyses of the long bones were enlarged and the ribs were beaded in "rosary" fashion. The skin and subcutaneous tissues were hypertrophied, causing an exaggeration of the natural folds of the skin. The abdomen was prominent and the fœtus as a whole was very obese. Finally, there was epicanthus, the lips, tongue, and eyelids were thickened, the tongue protruded from the mouth, and there were decided prognathism and flattening of the entire nasal region—a group of conditions which simulated closely the features of congenital cretinism. Dr. Nathan found characteristic disturbances of development of the body of the sphenoid, the basilar part of the occipital, the ethmoid, and the nasal bones which caused the peculiarities of cranial and facial physiognomy of chondrodystrophia fœtalis. The long bones showed a peculiar affection of the growing cartilage in every case—viz., increased vascularity, a more or less complete arrest of the normal formation of rows of cartilage cells which precede the deposit of osseous tissue proper in a growing bone, and a softening of the cartilage almost to a gelatinous condition favouring deformity. Illustrative photographs are reproduced of Dr. Nathan's cases and he adds, "the hair on the head is abundant, fine and soft, not brittle." The legs are shortened out of all proportion to the trunk, unlike cretinism, where both are shortened. The mental faculties are always intact, the gait is steady and not peculiar, and the patient learns to walk and to talk like other children. As the patient gets older the obesity disappears. Chondrodystrophia fœtalis is also different, says Dr. Nathan, from the Mongolian type of idiocy. Finally, no lesions or changes of the thyroid gland have been found in this affection, whereas it is atrophied or defective in cretinism. The three conditions—chondrodystrophia fœtalis, congenital cretinism, and congenital rickets—are entirely different from one another.

THE BEHAVIOUR OF ENTERIC FEVER IN PRUSSIA.

THE council of the Epidemiological Society is to be congratulated cordially upon its recent departure in inviting distinguished epidemiologists from other countries to read papers at its meetings. We published in the columns of THE LANCET of April 23rd the full text of a paper read before that society by Dr. Reincke, the able medical officer of health of Hamburg, upon the behaviour of enteric fever and cholera in that great commercial city, and we are glad to hear that the society is this week entertaining Dr. Moritz Pistor of the Ministry of the Interior of the Kingdom of Prussia at its annual dinner. Dr. Pistor is reading a paper before the society to-night (Friday) at 11, Chandos-street, Cavendish-square, W., the subject of the paper being the Prevalence of Enteric Fever in Prussia during the Decade 1892–1901. Some of our epidemiologists are somewhat prone to take a rather insular view of certain infectious diseases and to generalise too widely upon the limited experience of this country. It is only by a careful study of the behaviour of communicable diseases under varying social and climatic conditions that the real etiology of such diseases can be elucidated and it is much to be hoped that the Epidemiological Society will continue its efforts in the direction of international epidemiology. The Transactions of the society contain contributions from most parts of the empire and from many parts of the world, yet it is but rarely that these papers have been delivered by the authors in person.

THE SUNSHINE OF ENGLAND AND SWITZERLAND COMPARED.

IT is very doubtful whether the amount of bright sunshine actually recorded in Switzerland and the southern counties of this country has ever previously been compared and the following figures cannot be considered otherwise than extremely striking. They demonstrate clearly that although on some parts of our south-west coast there has been less sunshine than during an average April and that in other places the month was not exceptionally bright, the most favoured portion of this country was so superior to one of the most favoured spots of the continent that it had from 35 to 80 hours more sunshine at a period of the year when the direct rays of the sun have such an incalculable influence upon the public health. There are unfortunately no averages available with which to compare the Swiss values but it is an undeniable fact that the weather in that country during the past month was not at all of a rainy or unsettled description. Even London, which is noted above all places for its lack of bright sunshine, was brighter than most of the Swiss resorts and had 32 more hours than Basle. Only the statistics for the south-west, south, and south-east of this country are given in the appended table, but at other localities further north, where the hours of sunshine have been less numerous, they exceeded those in Switzerland. At Aberdeen, for instance, there were 157 and at Llandudno and also at Nottingham 162 hours of sunshine. It is probably nothing but an unusual coincidence that the stations with the least altitude had both the greatest and the least sunshine. Lugano had 158 and Basle only 106 hours of sunshine.

April Sunshine in the South of England and in Switzerland

THE WORKING OF THE MIDWIVES ACT.

AN interesting report on the action taken in carrying out the provisions of the Midwives Act has been presented to the Midwives Act committee of the Lancashire County Council by its medical officer, Mr. E. Sergeant. In February last the committee determined that a short advertisement should be inserted in 56 of the newspapers circulating within the county to the effect that "every person desirous of practising in the administrative county of Lancaster as a midwife must forthwith send in her name to the medical officer, Preston." Up to April 6th applications to be placed on the register have been received from 354 persons residing in the county districts. Of these 96 held certificates of examining institutions recognised by the Central Midwives Board and 305 claimed to be placed on the roll as having been in *bonâ-fide* practice as midwives for at least one year previously to July 31st, 1902; in addition 96 who had applied in mistake, were referred to their own authorities. A list of applicants is furnished by Mr. Sergeant showing the number from each of the county districts and also the number of midwives practising at the present time in these districts as shown by the lists supplied by the medical officers. An examination of this return shows that while the lists of the medical officers contain some 1069 names only the small proportion of 378 of these up to the time the report was furnished—viz., April 6th—had applied for registration. Possibly many of the women will apply before April 1st, 1905, after which date they will no longer be able to call themselves midwives according to the provisions of the Act. No doubt many from ignorance of the requirements of the new Act or from carelessness will fail to avail themselves of the privilege of having their names enrolled on the register as having been in practice as midwives, and we foresee that the local authorities will have a good deal of trouble in dealing with these women when the limit of time expires. Mr. Sergeant's report is of interest as showing the relatively small number of midwives in the county of Lancaster who have so far responded to the invitation of the county council to enrol themselves.

INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Café Monico, Piccadilly-circus, on Thursday, June 9th, at 7.45 P.M., when Surgeon-General Sir Colvin Colvin-Smith, K.C.B., will preside. Officers intending to be present should communicate with the honorary secretary, Lieutenant-Colonel P. J. Freyer, 46, Harley-street, London, W.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

IN the seventh lecture on the sporozoa, delivered by Professor E. A. Minchin at University College, London, on May 2nd,[1] the group of sporozoa known as the microsporidia was dealt with. The microsporidia constitute an order separate from the myxosporidia. They are characterised by being cell parasites living within cells or in the interstices of solid tissues but they are never found free in the visceral cavities as is the case with some of the forms mentioned in previous lectures. The trophic stage is in some marked by a large spore-producing form of body, in others by extreme minuteness. The spores produced are in every case of very minute size, sometimes being almost invisible. In specially stained specimens a single polar capsule can be seen. These little spores, in the form of minute oval bodies, are met with in insects and occasionally in fishes but they do not occur in warm-blooded vertebrates. In this respect they differ from the sarcosporidia which are parasitic on the higher warm-blooded animals. In the angler-fish and the stickleback tumours of round or ovoid form are occasionally seen in the tail, fins, and ocular region, while in the flounder cysts are produced in the gall-bladder, the cause of these tumours or cysts being the presence of a species of microsporidium in the tissues. Some of the microsporidia are parasitic on the silkworm and prove to be very deadly. The ordinary "silkworm disease" is due to a form (microsporidium or glygea bombycis) which infests the caterpillar and the mulberry trees on which it feeds. Professor Thélohan of Paris has shown that crayfish in France are liable to infection by species of microsporidia which grow within the muscles in such numbers as to cause death and extermination of the crayfish in several rivers. The life cycle of the microsporidia comprises a stage of partial budding like the torula of yeast (partial schizogony or merogony) and the sporulation stage which follows this. Each spore divides itself repeatedly until eight oval-shaped daughter spores result, each of which is provided with a long stinging thread. The microsporidium which occurs in the stickleback is a large parasite with many nuclei. It undergoes a peculiar form of sporulation, ending with the formation of minute sickle shaped spores. The more important microsporidia, so far as concern the higher animals or human industries, are glygea bombycis (the disease of the silkworm) and the thelohania which affects the crayfish. The sarcosporidia are another group of sporozoa which has been as yet little studied. They occur in warm-blooded animals, such as the pig, sheep, mouse, and occasionally man. They occur rarely in cold-blooded animals. They were first discovered in the mouse by Miescher. The parasite dwells within the muscular fibre of the animal. The life cycle includes a multinuclear phase comparable to that of glygea bombycis and a stage of spore formation in which numerous sickle-shaped young spores are produced. Mice infected by feeding with the spores of sarcosporidia exhibit symptoms of illness only after a long incubation period during which the parasite probably undergoes a series of trophic changes before it becomes an active spore producer. Laveran and Mesnil also found microsporidial parasites in the sheep. A form identical with that in the sheep occasionally infects man. It is probable, concludes Professor Minchin, that further research will show that the sarcosporidia are important agencies in the production in the human subject of disease—i.e., disease hitherto unsuspected to be due to such agencies and but little investigated.

"DR." BELL AND THE POST-OFFICE.

FOR about the two-hundredth time we have received one of "Dr." Bell's filthy little pamphlets which has been forwarded to us by a correspondent who is anxious to know if the circulation of such literature cannot be stopped. We have more than once applied to the police authorities who say that they can do nothing, but on May 5th a man named George William Burgess was summoned before Sir Horatio Davies at the Mansion House police-court for sending certain objectionable prints through the post. The Alderman said that he should not be doing his duty if he did not do his best to put a stop to a business of this kind and Mr. Burgess was fined £10. Now, if one man can be summoned and fined for sending objectionable prints through the post there is no reason why another should not be punished likewise, and we should like to ask the police authorities and the Postmaster-General why they continue to allow the man who calls himself "Bell" to send his filthy literature through the post. We may remind our readers that on Jan. 28th, 1896, "Bell," whose name was then "Henry Walters," was fined £20 and six guineas costs for using the titles "M.D." and "Dr." without being a duly qualified medical man. He still continues to call himself "Doctor," he still sends his dirty little pamphlets broadcast, and he still gives testimonials purporting to come from medical men whose names, however, do not appear on the Medical Register.

THE ACTION OF MINERAL WATERS.

THERE is among medical men a lack of unanimity as to the way in which the beneficial results obtained in certain cases by the use of mineral waters are brought about. Some attach importance to the exact composition of the water and regard subtle differences in the proportions of the various salts contained in it as of the greatest consequence, while others incline to the view that it is the quantity taken rather than the quality of the fluid which matters and suggest that what is chiefly accountable for the progress made by those undergoing a "cure" at some health resort is the alteration involved in the mode of life of the patient or the habit of temperance which he is constrained to adopt. Light is perhaps thrown upon the subject by a communication made to the Académie des Sciences at Paris by M. F. Garrigou at the sitting of April 25th. He has observed that certain mineral waters contain organic matter in two forms—a crystalloid and a colloid. The heavy metals present are associated with the colloidal substances, which latter constitute what he describes as "*oxydases naturelles.*" Those patients whose tissues have lost their oxidising power as the result of debilitating infectious disease and anæmia derive benefit from the employment of a water containing traces of the heavy metals with their accompanying colloids—e.g., the waters at Eaux-Bonnes—since these oxidise the nitrogen which the tissues are unable to cope with and cause a great increase in the amounts of urea and uric acid excreted. This explanation, of course, will only cover a few of the numerous varieties of water used medicinally but it may afford some hint as to the *modus operandi* of the large groups of saline and alkaline waters the use of which has become so widespread.

---

[1] References to the previous lectures will be found in THE LANCET of March 12th, p. 736, and 26th, p. 889, April 2nd, p. 950, and 9th, p. 1009, and May 7th, p. 1296.

MALARIA IN EGYPT.

IN the notice of Lord Cromer's report on Egypt which we published in THE LANCET of April 30th, p. 1228, want of space precluded reference to his remarks under the heading "Fever at Ismailia." "I wish to draw public attention," he says, "to the very remarkable hygienic results which have been obtained at Ismailia by the application of Major Ross's plan for the destruction of mosquitoes." The town of Ismailia was founded in 1862 and until 1877 the public health remained satisfactory. Various works were then undertaken in the neighbourhood, one of the effects of which was a considerable increase in the area of stagnant water. Malaria then showed itself and before long the disease became endemic. During the 14 years from 1884 to 1897 the yearly average number of cases was 1700 out of a population of about 8400, of whom about 1800 were Europeans. Large sums were spent with the intention of improving the sanitary condition of the town not only by the Suez Canal Company but also by the Egyptian Government, "still no impression was made on the fever." The yearly average number of cases during the five years from 1898 to 1902 was 1800. The President of the Canal Company then invited Major Ross to visit Ismailia and to report on the situation and on Dec. 27th, 1902, it was decided to give effect to his recommendations. To show the results Lord Cromer supplies the following table :—

Number of Cases of Malarial Fever at Ismailia.

—	1902.	1903.
January	162	13
February	100	20
March...	101	16
April	621	14
May	133	9
June	154	15
July	120	23
August	130	18
September...	176	25
October	159	39
November	176	12
December	73	9
Total	2105	213

Words could add little to the eloquence of these figures and yet, as Lord Cromer points out, the facts are even more remarkable than would at first sight appear. Out of the 213 cases which occurred in 1903 no fewer than 203 were relapses. The number of fresh cases during the twelvemonth was consequently only ten. "There is," says Lord Cromer in conclusion, "one point in connexion with this branch of the subject which is worthy of note. Expert authorities are agreed in holding that mosquitoes do not range far from the place where they are bred. It would therefore appear possible for a few neighbours to coöperate together and free their special locality from this insect pest. The experiment is now being tried in the quarter of Cairo in which I reside. In order to encourage other residents in Egypt to follow the example of my neighbours and myself I may mention that I am informed that it has become possible to dispense with mosquito curtains at Ismailia."

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE next general or quarterly meeting of this association will take place, under the presidency of Dr. Ernest W. White, on Wednesday next, May 18th, at 4 P.M., at the Langham Hotel, Portland-place, London, W. The following papers will be read: Quantitative and Qualitative Leucocyte Observations in Various Forms of Insanity, by Dr. Lewis C. Bruce, physician-superintendent, and Dr. A. S. M. Peebles, assistant physician, Perth District Asylum, Murthly; a Statistical Note on the Social Causes of Alcoholism, by Dr. W. C. Sullivan; the Psychology of Hallucinations, with diagrammatic illustrations, by Dr. W. H. B. Stoddart; and Notes of a Case of Combined Spinal Degeneration with Unusual Mental Symptoms, with microscopical sections of the cord, by Dr. J. Kennedy Will. The members will afterwards dine together at 6.30 P.M. at the Café Monico, Regent-street, W. Further information can be obtained from Dr. Robert Jones, the honorary general secretary, 11, Chandos-street, Cavendish-square, London, W.

THE annual dinner of the British Balneological and Climatological Society will take place on May 18th at the Criterion Restaurant, Piccadilly, London, W., at 7.30 P.M. After the dinner there will be a smoking concert by invitation of the President. Further information may be obtained from the secretaries, Dr. Septimus P. Sunderland, 11, Cavendish-place, London, W., or Mr. H. Shirley Jones, "Ravenstone," St. Andrew's-road, Droitwich.

THE Right. Hon. C. Scott Dickson, K.C., M.P., Lord Advocate for Scotland, will preside at the dinner of the Glasgow University Club, London, to be held on Friday, June 3rd, at the Café Royal, Regent-street, London, W. Applications for tickets should be made to the honorary secretaries, 63, Harley-street, W.

Mr. George Herring, who during the past five years has contributed £53,000 to the Metropolitan Hospital Sunday Fund, has again offered to give either £10,000 to the Fund or to add one-fourth of the amount collected in places of worship on June 12th, limiting this to a collection not exceeding £100,000.

THE oration of the Medical Society of London will be delivered by Sir Isambard Owen on May 16th at 8.45 P.M. in the rooms of the society, 11, Chandos-street, W. The subject is the Future of Medical Education in London.

THE death is announced on May 1st at Leipsic of Wilhelm His, the eminent professor of anatomy in the university of that city. We shall publish an extended account of his career in a future issue.

NEXT January the University of Kharkoff will celebrate its hundredth anniversary with an exhibition of documents and various objects of interest connected with the life of the institution.

THE Harveian Oration will be delivered on Tuesday, June 21st, by Dr. Richard Caton, at the Royal College of Physicians of London, Pall Mall East, at 4 P.M.

Sir George Hare Philipson, M.D. Cantab., M.D. Durh., D.C.L., LL.D., has been elected president of the Newcastle Royal Infirmary.

THE Moscow Physico-Medical Society will in the month of October this year celebrate its hundredth year of existence.

THE ANTIVIVISECTIONISTS AND THE "JUNGLE THEORY OF MORALS."

THE antivivisectionists issue "a humane monthly journal" which they entitle the *Animals' Guardian.* Humanity in this case seems to consist in seeking to prevent the progress of such scientific research as is most likely to lead to the discovery of the cause of disease and the best means for its cure or prevention. Nor does this paper display any greater concern for the available scientific methods of saving the life and health of the animals of which it has most fallaciously entitled itself the guardian. Persons really desirous of acting as the guardians of animal life would naturally devote themselves to the study of the very elaborate scientific researches made for the prevention of cattle plague and other epizootics. From all parts of the world calls have been made on such men as Professor Koch or the eminent bacteriologists of the Pasteur Institute. For anthrax among the sheep in Australia, for cattle disease in South Africa, and for cattle plague to-day in Egypt eminent men of science have gone to study on the spot these devastating epizootics. With the aid of the knowledge acquired by vivisection they have produced antitoxins that have saved millions of animals. A journal professing to be "the animals' guardian" should be teeming with information in regard to these researches. All its eloquence should be devoted to extolling the virtues and the achievements of those who, with the aid of vivisection, have done so much to save the lives of men and animals. As the paper is illustrated we might expect to find in it the portraits of Koch, of Pasteur, of Claude Bernard, of Lister, and of the many other eminent men whose scientific researches have so largely contributed to reduce the sufferings of both man and beast.

This is not, however, the antivivisectionist's conception of "a humane monthly." For illustration he prefers the head of a savage tiger which picture he dedicates, by a special inscription printed underneath, to the Society for the Advancement of Medicine by Research. Then marked copies of this particular number have been sent to persons known to uphold vivisection. The article that accompanies the tiger's head is written by the editor and infers that this tiger is meant to be the portrait of vivisectors and their supporters. Apparently the latter have very little to say for themselves for we are told that they invariably quote the same thing—namely, Tennyson's line on "Nature red in tooth and claw." Then this learned and polite editor of the "humane monthly" kindly explains how the vivisector's theory of morals is that of the jungle, where wild beasts "seek their meat" by preying upon each other. We are further informed: "Defenders of vivisection, intrenching themselves behind the jungle concept of morals, are appealing to the savage instincts of primitive man. Innate human savagery finds fitting expression in the savagery of the jungle. 'Deep answereth unto Deep.' Both follow their instincts, but—the lower beast is not morally culpable because he has no moral responsibility, not being a rational being. Even if nature be cruel that cannot be any justification to a man in carrying on such a practice as vivisection. For do we not spend our days in opposing nature and putting a curb upon her?" Then the conclusion is: "To sum this question up, the vivisector's appeal to the cruelty of Nature, alleged or real, is an appeal to the non-moral law of the jungle."

Thus we are left to infer that the portrait of the tiger is symbolical of the character, the morals, and the general disposition of the vivisector and his partisans.

That such balderdash should be treated with contempt by the world of science is but natural. It is humiliating to have to stoop to deal with such flagrant manifestations of crass ignorance. Unfortunately, the question at issue is not wholly in the hands of the learned section of the community. These absurd pictures do appeal to ignorant sentimentalists. The latter are not likely to reflect, otherwise it would be obvious to them that tigers do not practise vivisection. It is equally certain that tigers do not apply anæsthetics when they devour alive any animal that they can catch. On the contrary it is precisely the scientific investigator who, when obliged to cut or to kill, does so with every care to prevent unnecessary suffering. He it is, too, who daily studies nature the better to put "a curb upon her." The jungle theory of morals is to leave things alone and to let disease prey upon us and the animals, and to permit the strongest to kill the weakest. Science, on the contrary, drains the jungle, tames or destroys the wild animals; studies, analyses, dissects, vivisects—in fact, employs all available means to unravel the laws of nature and to learn how to apply them, not to destroy and to devour, but to protect and to save both the weak and the strong, both man and beast. The tiger doubtless objects to this and so does the antivivisectionist but it is nevertheless what man calls human and humane progress.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the election of members of the Council on the first Thursday in July there will be three vacancies. Three members of the Council retire every year and this year it is the turn of Mr. T. Bryant, Mr. T. Pickering Pick, and Mr. J. Tweedy to retire. Mr. Bryant's third term of office, 24 years in all, will then come to an end and we believe that he does not intend to offer himself for re-election. Mr. Pick has already resigned, as he has left London. In ordinary circumstances Mr. Tweedy's term of office would end in July but as he will be President on the day of election his term of office lasts for another year. Thus only two vacancies occur in the natural course. The third vacancy is occasioned by the death of Mr. T. R. Jessop. This year three new members of Council, assuming that neither Mr. Bryant nor Mr. Pick will apply for re-election, have to be appointed. It is certainly unusual to have so many vacancies with no old member applying for re-election and we shall therefore expect a large number of candidates.

ASYLUM REPORTS.

The District Asylum, Ballinasloe (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 1210, comprising 733 males and 477 females. The admissions during the year amounted to 240—viz., 135 males and 105 females. Of these, 198 were first admissions. The report of the late Mr. R. V. Fletcher, the medical superintendent, states that in 37 of the cases admitted the mental disease "had existed for over 12 months and the delay in seeking efficient treatment is without doubt injurious to the prospect of recovery." Moreover, 26 of the patients admitted "were over 60 years of age and likely therefore to remain permanently" as chronic and incurable cases. The number of patients discharged as recovered during the year amounted to 85—viz., 53 males and 32 females, or 7 per cent. of the average number resident. The deaths during the year amounted to 80, or 6 6 per cent. as calculated on the same basis. Of the deaths, three were due to dysentery, five to bronchitis, five to cardiac disease, eight to epilepsy, 13 to senile decay, 20 to pulmonary tuberculosis, and the rest to other causes. The high death rate from pulmonary tuberculosis "is due to the overcrowding which prevailed in the early part of the year before the new hospital was opened." "The experience of asylum physicians," the report continues, "is generally in favour of segregating the epileptics, and this idea is still further developed abroad in Germany and the United States, where special asylums or colonies for epileptics have been established with marked beneficial and curative effect. The establishment in Ireland (by groups of counties) of such asylums and colonies could not but tend to the comfort of the sufferers, afford opportunity for the wider study of the disease, and relieve the admitted congestion of district asylums without appreciable increase of cost." At the close of the year the number of persons suffering from imbecility and idiocy in the asylum was found to be 58. "It is much to be regretted that the younger persons of this class cannot in Ireland be sent to a training institution for imbeciles, where their capacity for improvement might be developed." The inspector of lunatics states in his report that the day-rooms and dormitories were bright and cheerful and afforded ample cubic space for the occupants, that the patients were quiet, contented, and well behaved, that overcrowding existed as regards sleeping accommodation, a condition which called for speedy remedy, and that the medical case-books and records were well and carefully kept. A recommendation is also made that the committee should consider *the importance of providing* the necessary fittings and apparatus for the pathological room of the institution "so that the medical officers may be able to take advantage of this great field for scientific study."

Looking Back.

FROM.

THE LANCET, *SATURDAY*, May 13, 1826.

INFLAMMATION of the iris first received the name of iritis from J. A. Schmidt, of Vienna, who published a small but admirable description of the affection in 1801. When the clear account of the phœnomena, symptoms, progress, and consequences of this inflammation, contained in the work of Schmidt, is contrasted *with the entire* ignorance which then prevailed, in this and other countries, on the same subject, we shall become sensible how far the Germans have preceded all other nations in cultivating the ophthalmic department of our profession. A good analysis of this essay, which is in the German language, may be seen in the first volume of the Quarterly Journal of Foreign Medicine and Surgery; the intelligent writer gives a general account of the views entertained by the German practitioners on the subject of iritis.[1]

AT a general Meeting of the LONDON OPHTHALMIC INFIRMARY, held on the 18th of June, 1823, it was resolved—"That certificates to pupils be in future countersigned by the Chairman, or by the secretary, and registered by the latter; that a fee of five shillings be paid and set apart towards the *increase of the library*." Three years, within a month, have now elapsed, since this resolution was adopted, *and yet, not a single book has been purchased*, either for the use of the surgeons or of the students. As the money is ordered to be set apart, we should like to know where it is collecting, and who have the control of the fund.

Is it true that Dr. FARRE receives ONE THIRD of the fees paid by students for witnessing the SURGICAL PRACTICE? If so, it certainly is a most liberal reward for a *triennal rhubarb prescription*; this is indeed, FARRE *fetched* liberality, and caps, with one exception, every thing of the kind with which we have the happiness to be acquainted. The exception we allude to, is to be found in the ST. GILES'S INFIRMARY, where the *nominal* surgeon (fascinating creature!) positively OGLES the Governors out of one hundred guineas a year; whilst the *actual* surgeon who performs, in a most efficient manner, all the duties of the charity, cannot TWEEDLE them out of one hundred pence. Verily the *charitable* institutions of this metropolis are queerly conducted.[2]

MEDICINE AND THE LAW.

Reckless Exposure of Others to Infection.

AT Derby recently a flagrant and somewhat unusual case of the reckless exposure of others to infection was suitably punished by the infliction of a fine of £5 with the alternative of one month's imprisonment. The culprit was a Captain Feilden, stated to be a well-known resident, who appears to be the proprietor or compounder of an "ointment." With the idea of exhibiting the virtues of this salve he visited three houses where there were cases of small-pox and it was mentioned before the magistrate that he recommended the inmates of one of these dwellings not to permit the officers of the local health authority to enter. Having paid his visits he went about his usual avocations without any change of clothes or any disinfection of the garments which he was wearing, and being, fortunately for his neighbours, detected in this the punishment mentioned has been meted out to him. He may count himself lucky that no case of infection was traced to his negligence, for in such an event he would presumably have incurred a heavy civil liability in addition to a possible increase of the penalty inflicted.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on May 3rd, Dr. T. S. CLOUSTON, the President, being in the chair.

The Curator submitted his report for the last year regarding the research and reporting work undertaken in the laboratory during the year and the expenditure incurred. The report showed that 35 workers had been engaged in research; that 2365 specimens had been reported on, being an increase of 497 on the number for the previous year; and that the expenditure had amounted to £1038 1*s*. 6*d*. The report was adopted by the College.

By a vote of the College Allan Douglas Cameron, a Licentiate of the College, was expelled from the College and deprived of his Licence to practise as granted by the College and of all his rights and privileges as Licentiate.

On a motion by the PRESIDENT the College instructed the Council to take action in favour of a clause being inserted in the Education Bill for Scotland providing for medical inspection of schools, so that school hygiene and the physical education and condition of the school children may become part of the educational system of the future in Scotland.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Borough of Crewe.—There were 64 stillborn children buried in Crewe in 1903, the proportion of stillbirths to total births having been 4·4 per cent. Dr. A. J. Laird criticises adversely the fact that the registration of stillbirths is not required and that such bodies are frequently buried on the certificate of a midwife or a nurse. He also quotes the county medical officer of health to the effect that "under the present system there appears to be nothing to prevent an infant who has lived a few minutes or a few hours being clandestinely conveyed to a nameless grave without the cause of death being certified or inquired into. It is also obvious that through there being no regular register for stillbirths concealment of births is facilitated." In connexion with this question of infantile mortality generally Dr. Laird expresses the opinion that "the only educational measures which promise any benefit are the frequent visits of sanitary inspectors and, most important of all, the teaching of schoolgirls the elements of hygiene and the proper management and feeding of infants." We are glad to read further on in this report that recently a considerable amount of attention has been given to the elementary schools and that the local education authority is about to remedy all the defects which have been discovered. More light, ventilation, and cubic space are apparently required in many instances and two of the schools are likely to be closed altogether. Doubtless, Dr. Laird will also urge upon the education authority the importance of the periodical inspection of the scholars and of a well-directed system of physical education.

The Borough of Hove.—Dr. Augustine Griffith, in referring to the important subject of infantile mortality and to the connexion which such mortality bears to improper feeding, has drawn up leaflets which are left at houses where births have taken place and which in simple language explain the principles that should govern the feeding of infants. Dr. Griffith also urges the importance of educating girls in the preparation of food and in the management of children. We referred in a recent leading article on the Education Act and Physical Fitness[1] to the importance of taking action in our schools with respect to the education of girls in these particulars and we hope that the matter will have the attention of every medical officer of health. An interesting illustration is furnished in the report before us of the importance of cooking mussels even although such cooking may not always amount to complete sterilisation. The mother of a family boiled some mussels for her husband, her children, and herself and all partook thereof. The mother was subsequently attacked with enteric fever and she eventually admitted that she had eaten a few of the mussels in a raw state. Presumably there was no other cause more likely than this to account for the attack.

---

[1] Excerpt from lecture on the Anatomy, Physiology, and Diseases of the Eye by Mr. Lawrence, *delivered in the London Ophthalmic* Infirmary, Moorfields.

[2] Editorial observations.

[1] THE LANCET, April 9th, 1904, p. 1004.

St. Thomas's Rural District, Exeter.—Mr. Mark Farrant reports the fact that in a certain house in his district there have been six cases of enteric fever, the cases having occurred in this fashion—one in 1898, two in 1899, two in 1901, and one in 1903. The house is built almost on the solid rock and the sanitation and water-supply are, it appears, quite satisfactory. Mr. Farrant thinks it possible that infection may have remained in the bedding, although it was disinfected on each occasion. This repeated invasion of one house is, in our experience, not so uncommon as is believed. We have ourselves seen numerous instances of it and there has in all cases been evidence pointing to the conclusion that disinfection had not been thoroughly carried out. The necessity for disinfection after cases of enteric fever does not appear to be recognised so generally as the facts merit.

Stockton Rural District.—Mr. J. W. Blandford has strong views with regard to the alleged deterioration of the working classes. He regards the deterioration, which he apparently accepts as a fact, as due in large measure to the defective feeding of infants and to the tendency on the part of mothers to forego the duty of suckling their offspring. He adds, "If the people would as carefully consider what is the best way of feeding for developing the human animal as farmers must do to make a profit out of the feeding of their animals, the general physique of the population would improve quite as much as it has done in the beast and sheep. The question of proper feeding is not so much a question of increased cost as a knowledge of what to feed on and how to prepare it." There is of course a good deal of truth in this statement, but it has to be remembered that in cattle breeding artificial selection is largely practised and we are not likely to arrive at this form of control in the human species for some years to come.

Taunton Urban District.—Epidemics of measles and whooping-cough occurred in this district during 1903 and Dr. H. J. Alford deplores the small amount of attention which is paid to these two diseases by the parents as compared with the panic which arises in connexion with any illness having the affix "fever." Possibly it might really be worth while in order to impress the serious nature of measles upon the people to apply the term "spotted fever" to it. Dr. Alford also deplores the fact that nearly all the infants' lives are insured and he holds the opinion that the practice of insurance in this sense should be put a stop to.

Burgh of Govan.—Dr. James Barras thinks that no appreciable reduction in the death-rate from tuberculosis will take place until the public are convinced of the infectious nature of the disease, but on the opposite page he furnishes figures which seem to show that from 1864 to 1868 tuberculosis caused 23·6 per cent. of the total deaths whereas in 1899 to 1903 the percentage was but 12·8. The tuberculosis death-rate per 1000 of the population does not appear to be furnished but the general death-rate of the population has fallen from 33·0 in 1864 to 18·9 in 1903 and the population has increased from 9058 in 1864 to 91,103 in 1903. In 1864 there were 65 deaths from tuberculosis, in 1903 there were 214. Another illustration of the desirability of boiling cockles before consuming them is contributed by Dr. Barras. A family consisting of four persons ate cockles at a watering-place on the west coast of Scotland, all the cockles being consumed in the raw state. These four persons after the usual period of incubation developed enteric fever and two of them (father and son) died. About the same time other cases were brought to notice and it was found that they, too, had consumed similar shell-fish. The family first referred to brought home cockles for their friends and these were divided amongst four families in the burgh. In each of these families one member who had alone partaken of the cockles in a raw state developed the disease, while the remaining eight persons who had boiled the cockles for from five to ten minutes all escaped. Two other persons who took both cooked and raw cockles were indisposed for several days with diarrhœa, &c. This appears to be a strong chain of evidence tending to incriminate the cockles, and this suspicion is still further strengthened by the fact that the molluscs were collected from a foreshore which was apparently obviously liable to pollution. The fact that the examination of cockles collected from the same locality as those which were consumed in the cases in question revealed "the presence of the bacillus coli communis" does not in view of the report of the Royal Commission on Sewage Disposal and of Dr. A. C. Houston's appendix thereto amount to very much, but the fact that some of the cockles contained the bacillus of enteric fever in great numbers is conclusive evidence that the cockles which are believed to have caused the disease were exposed to the risk of specific pollution. Having regard, however, to the difficulty in demonstrating the presence of this bacillus in shellfish it would have been well had the precise methods used by the bacteriologist been set forth.

The Borough of Lowestoft.—A case of small-pox occurred in the district during the summer of 1903 which illustrates the importance not only of providing isolation accommodation for cases of this disease but also of appointing a medical superintendent to such hospital. A visitor from Cambridge developed small-pox at Lowestoft and the medical attendant sought the assistance of Dr. A. Marshall, the medical officer of health, who at once removed the case to the small-pox hospital, situated about four miles from Lowestoft. But the medical attendant who had been called in refused to attend the case, as also did the medical officer of health in whose district the hospital was situated, and finally Dr. Marshall felt morally bound to attend the case himself. This is a somewhat unsatisfactory state of affairs and we trust that this incident has led to the appointment of a medical superintendent, or at least some medical practitioner whose duty it is to attend the cases in the hospital. We are, however, glad to see that the corporation appreciated the timely assistance of Dr. Marshall and also that the patient and her husband expressed to him their gratitude for his kindness.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8403 births and 4359 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had been 17·6, 16·0, and 16·3 per 1000 in the three preceding weeks, declined again last week to 14·9 per 1000. In London the death-rate was 14·9 per 1000, which was also the mean rate in the 75 other large towns. The lowest death-rates in these towns were 4·3 in Smethwick, 5·2 in Leyton, 6·0 in Burton-on-Trent, 6·2 in Devonport, 6·7 in Willesden and in East Ham, 7·8 in Tottenham and in King's Norton, and 8·0 in Walthamstow; while the highest rates were 18·6 in Liverpool, 19·4 in Wigan, 20·0 in Salford, 21·3 in Blackburn, 21·5 in Plymouth, 23·1 in Manchester, 23·7 in Merthyr Tydfil, and 26·5 in St. Helens. The 4359 deaths in these towns last week included 514 which were referred to the principal infectious diseases, against 530, 556, and 527 in the three preceding weeks; of these 514 deaths 195 were referred to whooping-cough, 158 to measles, 56 to diarrhœa, 51 to diphtheria, 32 to scarlet fever, 17 to "fever" (principally enteric), and five to small-pox. No death from any of these diseases was registered last week in Leyton, Bournemouth, Reading, Burton-on-Trent, Wolverhampton, Smethwick, Barrow-in-Furness, or Halifax, while the highest death-rates from the principal
infectious diseases wer
Manor, St. Helens,
Burnley, and Blackburn.
from measles occurred
Warrington, Manchester
Rhondda
Kings Nc
Manchaste.,
Swansea. The mortality from each of the other principal infectious diseases showed no marked excess in any of the large towns. Of the five fatal cases of small-pox registered in these towns last week one belonged to London, one to Stockport, one to Manchester, one to Tynemouth, and one to

Newcastle-on-Tyne. The number of small-pox patients remaining under treatment in the Metropolitan Asylums hospitals, which had been 144, 123, and 104 on the three preceding Saturdays, had further declined to 88 on Saturday last, May 7th; 14 new cases were admitted during the week, against 37, 23, and 12 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1590, against 1523, 1543, and 1541 at the end of the three preceding weeks; 242 new cases were admitted during the week, against 172, 210, and 185 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 295, 254, and 224 in the three preceding weeks, further declined last week to 193, and were 69 below the number in the corresponding period of last year. The causes of 47, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Newcastle-on-Tyne, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Ipswich, Birmingham, Liverpool, St. Helens, Manchester, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·9, 21·0, and 20·0 per 1000 in the three preceding weeks, further declined to 18·0 per 1000 during the week ending May 7th, but was 3·1 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·2 in Perth and 12·3 in Leith to 20·1 in Glasgow and 20·4 in Dundee. The 594 deaths in these towns included 25 which were referred to whooping-cough, 16 to measles, nine to diarrhœa, four to scarlet fever, four to "fever," three to small-pox, and three to diphtheria. In all, 64 deaths resulted from these principal infectious diseases last week, against 65, 79, and 71 in the three preceding weeks. These 64 deaths were equal to an annual rate of 1·9 per 1000, which was slightly in excess of the mean rate last week from the same diseases in the 76 large English towns. The deaths from whooping-cough, which had been 20, 29, and 22 in the three preceding weeks, rose again to 25 last week, and included 13 in Glasgow, six in Edinburgh, two in Dundee, and two in Paisley. The fatal cases of measles, which had been 21, 26, and 19 in the three preceding weeks, further declined last week to 16, of which 12 were registered in Glasgow and two in Greenock. The deaths from diarrhœa, which had been 15, 11, and 13 in the three preceding weeks, declined again to nine last week and included five in Glasgow and two in Dundee. The fatal cases of scarlet fever, which had been four and three in the two preceding weeks, rose again last week to four, of which three occurred in Glasgow. The three deaths from small-pox corresponded with the number in the preceding week, and included one in Glasgow, one in Paisley, and one in Greenock. The deaths from diseases of the respiratory organs in these towns, which had been 152, 115, and 121 in the three preceding weeks, declined again last week to 100, and were slightly below the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24 4, 23·3, and 20·8, per 1000 in the three preceding weeks, rose again to 23·1 per 1000 during the week ending May 7th. During the past four weeks the death-rate has averaged 22·9 per 1000, the rates during the same period being 15 8 in London and 16·6 in Edinburgh. The 168 deaths of persons belonging to Dublin registered during the week under notice were 17 in excess of the number in the preceding week, and included 18 which were referred to the principal infectious diseases, against 17, ten, and eight in the three preceding weeks; of these, 11 resulted from whooping-cough, four from measles, two from "fever," and one from diarrhœa, but not any from small-pox, from scarlet fever, or from diphtheria. These 18 deaths were equal to an annual rate of 2 5 per 1000, the death-rates last week from the principal infectious diseases being 1·8 in London and 1·1 in Edinburgh. The fatal cases of whooping-cough, which had been 11, five, and three in the three preceding weeks, rose again last week to 11. The deaths from measles, which had been four, three, and two in the three preceding weeks, increased again to four last week. The 168 deaths in Dublin last week included 38 among children under one year of age and 37 among persons aged 60 years and upwards; the deaths of infants considerably exceeded the number in the preceding week, while those of elderly persons showed a slight decline. Eight inquest cases and five deaths from violence were registered, and 56, or exactly one-third, of the deaths occurred in public institutions. The causes of five, or nearly 3 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. M. Page to the *Suffolk* on commissioning; J. Shand to the *Glory*, additional, for Wei-Hai-Wei; and H. O. Beatty to the *Boscawen*, for *Boscawen* (No. III.). Staff Surgeon L. Kilroy to Bermuda Hospital. Surgeons: *R. H. St. B. E. Hughes to the Hogue and to the Suffolk;* M. H. Knapp to Plymouth Hospital; N. S. Meiklejohn to the *Monmouth;* W. G. Westcott to the *Egmont*, for Malta Yard; G. F. Alderdice to the *Albemarle;* and T. D. Liddle to the *Exmouth* and to the *Prince of Wales.*

ROYAL NAVAL VOLUNTEER RESERVE.

John Alexander Campbell Kynoch to be Surgeon.

Scots Guards: Surgeon-Lieutenant-Colonel G. S. Robinson retires on retired pay (dated May 7th, 1904).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. W. Kenny to be Colonel on augmentation (dated April 1st, 1904).

Lieutenant-Colonel W. L. Lane retires on retired pay (dated May 11th, 1904).

The undermentioned Lieutenants to be Captains:—M. F. Foulds (dated April 9th, 1904); J. B. Clarke (dated April 14th, 1904); and D. L. Harding (dated April 26th, 1904).

Colonel G. D. N. Leake has been transferred from the Bombay and Nagpore Districts to the Oudh and Rohilkund Districts. Lieutenant-Colonel T. B. Tuckey (retired) is noted for appointment as medical officer in charge of the Cork Military Prison.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain H. D. Brook to be Surgeon-Major (dated April 23rd, 1904).

IMPERIAL YEOMANRY.

Denbighshire (Hussars): Surgeon-Captain R. Williams resigns his commission (dated May 7th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st West Riding of Yorkshire: Surgeon-Lieutenant P. J. S. Bird to be Surgeon-Captain (dated May 7th, 1904).

Rifle: 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant G. F. Whyte to be Surgeon-Captain (dated May 7th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Leeds Company: William McGregor Young to be Lieutenant (dated May 7th, 1904). The Manchester Companies: Captain J. B. Mann to be Major (dated May 7th, 1904).

BEARER COMPANY ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Sussex and Kent: James Augustus Rooth to be Lieutenant (dated May 7th, 1904).

THE KING'S BIRTHDAY.

The King's Birthday will be celebrated in London and at all Home Stations on Friday, June 24th next. At all Foreign Stations His Majesty's Birthday will be celebrated on Wednesday, Nov. 9th next.

PHILANTHROPY IN WAR.

The Times, apropos of voluntary aid to the sick and wounded in the Russo-Japanese war, alluded not long ago to the desirability of having a philanthropic organisation which only aims at an impartial alleviation of the sufferings of the combatants and is quite untainted by any race hatred or by any political or national prejudice. The subject is really one which deserves far more consideration than it obtains. To say nothing of the difficulty of apportioning aid in relief of the sick and the wounded in war equally and fairly between the belligerent forces there is another point which should not be altogether lost sight of. Such philanthropic movements and systems on the part of neutrals have the effect, in some measure at any rate, of relieving the belligerents of the cost and responsibility of war by freeing them from the care of their sick and wounded, and of throwing into the purchase of war material the sums saved in not having to provide for their wants, thereby enabling a general, it may be, to prosecute a campaign with greater energy, activity, and success. All will agree that the aim and the object as well as the work actually performed by Red Cross societies in time of war are most laudable and praiseworthy, [illegible] out of the Geneva [illegible] great. If we are to [illegible] aiding one of the [illegible] our benevolent efforts should be directed and confined to the relief of the sick and the wounded as such, and quite irrespectively of our sympathies with one side or the other in regard to nationality, race, creed, or politics. General Kuroki, telegraphing on May 3rd, reported that a careful search of Sunday's battlefield disclosed 200 dead and wounded among the Russians in addition to the number previously reported and he expected that more would be found when the searches of the Japanese medical corps were complete. The general added that among the prisoners was a medical field officer whom the Japanese ordered to assist in caring for the wounded Russians and Japanese. This officer at once obeyed and is now engaged in treating the wounded of both armies. That is the proper spirit and an illustration of the line to be followed.

THE WAR IN THE FAR EAST.

Whatever may be the final outcome of the present war in the Far East and whether Russia will be able hereafter to reverse the results or to repair the disastrous fortunes that have attended her arms up to the present time no one can say. But the strength, leadership, and tactics of the Japanese as compared with the weakness of their giant adversary have been such striking features of the war that no one could miss seeing them. We have no complete returns of the total losses sustained on either side in the various naval operations and engagements, but according to the official accounts of those on land in the recent fighting on the Yalu and in the subsequent retreat of the Russian forces it appears that the Russian losses are officially placed by General Kuropatkin at 70 officers and 2324 men killed, wounded, or prisoners. The Japanese return their losses at five officers and 180 men killed and 25 officers and 690 men wounded. According to the special correspondent of the *Standard* at Tokio the Japanese, as the result of the fighting on the Yalu, are said to have buried over 1300 Russians between Kiu-lien-cheng and Tang-shan, a distance of 20 miles. From a St. Petersburg telegram we learn that General Kuropatkin has requested the Russian Red Cross Society to supply 2000 more beds for the use of the military hospitals at the front.

ARMY ORDERS FOR MAY.

There are a few subjects of medical interest in the Army Orders for May promulgated by direction of the Army Council to which we may call attention, such as the following:—An amended regulation regarding pay and allowances of Queen Alexandra's Imperial Military Nursing Services and one regarding additional pay, corps pay, and extra duty pay of the non-commissioned officers and men of the Royal Army Medical Corps. Soldiers who are detained in hospital after discharge or transfer to the Army Reserve shall not be subject to hospital stoppages. Revised hospital equipment schedules have been approved. These schedules are confined to the hospitals shown therein. A scheme of centralisation under which important central hospitals only will be retained is now under consideration.

MILITARY DENTISTRY.

The subject of the care and the preservation of soldiers' teeth in our army has occupied of late the attention of the War Office in this country and a start has been already made in this direction by the appointment of some surgeon-dentists for our troops serving at home. Military dentistry is also receiving a considerable amount of attention at the present time in the German army where practical instructions have been issued and lectures given on the hygiene of the mouth and care of the teeth. Our service contemporary the *Broad Arrow* of last week has some timely remarks as to the importance of the subject as regards the health and efficiency of the soldier.

Correspondence.

"Audi alteram partem."

THE TENURE OF OFFICE OF THE MEDICAL OFFICER OF HEALTH.

To the Editors of THE LANCET.

SIRS,—The very nature of the employment of a medical officer of health, if he conscientiously does his work, subjects him to the risk of a want of appreciation from his council. It is true that tact will accomplish much for him, but sometimes no amount of tact is sufficient to mollify the ruffled feelings of a member of a council who has been put to considerable personal expense through the zeal of the medical officer of health. This possibility appears to have been foreseen by the framers of the Public Health Act of 1875, for that Act contains provisions intended to prevent that official being ousted from office by his local authority without sufficient reason. By providing for the payment of one-half of his salary from county funds—if the appointment is sanctioned by the Local Government Board—the Act puts him in the same position as a district medical officer of a union with regard to duties, tenure of office, &c.—that is, he cannot be dismissed from office by the local authority without the consent of the Local Government Board.

It is curious, however, that in many instances these very provisions for his security not only afford him no protection but actually render him more insecure than those other officials who are not so provided for. The spirit of the Act is set at naught by most local authorities by making the appointment for a limited time, generally from year to year. During the continuance of the year's appointment the officer's dismissal would have to be sanctioned by the Local Government Board. At the end of the year the appointment is vacant and it is open to any member of the local body to propose its advertisement or to move for the appointment of someone else. No reason for this course need be given except to his [illegible] familiar with [illegible] know that th[illegible] acquainted with one rural district council which numbers three members, so that an agreement between two of them would constitute a majority of the council.

It will be seen that the annual raising of the question of the re election of the medical officer of health yearly reminds the members of his authority that they have the option of electing him or not. I am personally acquainted with a case where this possibility of non-re-election was for years held as a threat over the head of the medical officer of health if he did this or if he did that. In the case of other officials who can be dismissed at the wish of the council the yearly question does not arise and their positions are to that extent the more secure. I have heard it represented that if all medical officers of health were appointed permanently one result would be that a number of existing inefficient officials would be secured in office to the detriment of their districts. It is just this type of medical officer who is already quite secure—the less he does the better he is liked. I venture to obtrude on your space on this matter because I feel certain that this is one of the factors at present tending to impede sanitary progress in many districts. It is not a question which personally affects me because my council has already made my appointment a permanent one.

I am, Sirs, yours faithfully,
E. H. SNELL,
Medical Officer of Health of Coventry.
May 10th, 1904.

To the Editors of THE LANCET.

SIRS,—As one who is vitally interested in this question I was glad to see two letters on it in THE LANCET of May 7th, both full of good points. Has it ever struck any of your readers th[illegible] inspector, [illegible] the only [illegible] years past it has been my desire to try the effect of the oil obtained from the pilchard as a substitute for cod-liver oil and in October, 1903, I asked Mr. Peck, the dispenser of the Hospital for Sick Children, Great Ormond-street, if he could obtain a sample of such oil. When the oil was first obtained I was informed that it could not be taken internally and on inquiry as to the reason I was informed "that a mistake had been made and that it could be taken internally and, in fact, was given to children in Cornwall as a substitute for cod-liver oil." I have not verified this statement. Having procured the oil it was necessary first to find out if the oil possessed any toxic properties and for this purpose I took some of the crude oil and also an emulsion which was prepared for me by the dispenser. I cannot say that either the crude oil or the emulsion was pleasant to take, but I do not think, if my memory serves me, that the taste was worse than the older preparations of cod liver oil. Certainly no unpleasant symptoms resulted saving the "repeat" which may, in certain individuals, occur with any form of cod-liver oil.

I then selected cases both from among the out-patients and in-patients to try the effect of the oil. I may say at once that some children, generally the younger ones, took it fairly well but it was resented by the older children who complained that "it was nasty and repeated." The sister and nurses also said that the children would not take it as readily as they would cod-liver oil. I then asked the dispenser if he could obtain a better and more refined sample of this oil and this he succeeded in doing. I tried this sample and certainly in appearance, smell, and taste it was preferable to the original sample. It made a good emulsion and I found the children took this much better. I may say that for the last six months I have had this oil in constant use, both in out-patient and in-patient practice, and have used it in all cases in which I considered cod-liver oil was indicated. The children who have taken it have, as a rule, done well and gained weight. Some children would not take it but I do not think this happened in any greater proportion of cases than occurs with cod-liver oil. Neither among the children in the wards nor among those in the out patients have I seen any bad symptoms which could be attributed to the "detrimental qualities of fish oil" and I consider the preparation quite as beneficial as the oil obtained from the cod. It is almost unnecessary to add that the oil is not prescribed as oleum morrhuæ but as oleum clupeæ, the name being derived from the family of the pisces clupeidæ to which the pilchard belongs.

I am, Sirs, yours faithfully,

FREDERICK E BATTEN,
Assistant Physician to the Hospital for Sick Children, Great Ormond-street.

May 9th, 1904.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—May I be permitted so far to correct the account of the meeting of the Metropolitan Street Ambulance Association which appears in THE LANCET of May 7th as to say that the remarks attributed to "Dr. F. W. Cock" on the subject of the New York ambulance system were really made by Yours very faithfully,

E. MARION COX, M.D., L.S.A.

Curzon-street, W., May 9th, 1904.

REMOVAL OF THE OVARIES FOR INOPERABLE CANCER WITHOUT EFFECT.

To the Editors of THE LANCET.

SIRS,—It is of great importance that all cases of removal of the ovaries for inoperable cancer should be recorded with a view to establishing the value of this operation.

Early in June, 1903, a woman, aged 43 years, consulted me concerning a swelling in her breast which she had had for some months. It was a well advanced scirrhus of the left breast. I admitted her into hospital on June 12th and next day removed the breast, cleared out the axilla as thoroughly as it could be done, and gave her thyroid gland for some months. She left the hospital on July 1st, 1903, in good health, though I feared that I should have her return some day as the cancer was so far advanced before operation.

On Jan. 8th, 1904, she returned with many nodules along the cicatrix. I readmitted her into hospital, explained the state of the case to her, and with her consent on Jan. 9th removed the ovaries as her menstrual functions were perfectly regular, and again gave her thyroid gland. I also used the Roentgen rays twice a week. She left the hospital on Feb. 4th well in herself and living in hope that the operation would cure her cancer. I could never see (although she attended the hospital regularly as an out-patient and continued her thyroid gland) that the operation made any impression in even retarding the growth of the cancer and on April 21st, 1904, she died.

I am, Sirs, yours faithfully,

Rugby, May 9th, 1904. CLEMENT DUKES.

THE ASSOCIATION OF DIPLOMATES OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.

To the Editors of THE LANCET.

SIRS,—May I ask you for space in THE LANCET to state that the general meeting of the above association will be held at 20, Hanover-square, London, W., on Thursday, May 19th, at 4 P.M. Circulars are being sent to diplomates in London and the provinces but as some may not receive them will they kindly accept this as an invitation to attend?

I am, Sirs, yours faithfully,

C. ST. AUBYN-FARRER,
Westbourne Park-road, W., May 10th, 1904. President.

SOUTH AFRICAN CIVIL SURGEONS' FOURTH ANNUAL DINNER.

To the Editors of THE LANCET.

SIRS,—May I call attention in your columns to the above dinner which will take place on Tuesday, June 28th, at the Hotel Cecil at 7.30 P.M.? Mr. G. H. Makins, C.B., will take the chair. As the addresses of those who served in the war are frequently changing I take this opportunity of catching the civil surgeon's eye. Reply cards will be sent out to all whose names and addresses are at my disposal and I shall be glad to hear as soon as possible from those who intend to be present. Tickets (price 10*s.* 6*d.*) should be paid for at the dinner. There will be a plan of the table in the reception room and those dining can thereby secure seats to suit their convenience beforehand. Miniature medals and decorations should be worn and guests are welcome.

I am, Sirs, yours faithfully,

44, Welbeck-street, W., May 11th, 1904. C. GORDON WATSON

CASE OF ECLAMPSIA WITH TWINS.

To the Editors of THE LANCET.

SIRS,—Mr. A. H. Haines's case of eclampsia in THE LANCET of April 9th, p. 1017, reminds me of a case I attended some time back. The patient was a primipara, aged 21 years. On my arrival at the house I found her in convulsions which had been going on for eight hours. I prescribed bromide and chloral and sought the assistance of a friend, Mr. C. H. Thackrah of Halifax, and on our arrival at the house we found the convulsions were in no way abated by the drugs. After a short consultation we decided to empty the uterus under chloroform. The anæsthetic was taken well and when the patient was well under the os was dilated by digital means, the membranes were ruptured, and the forceps was applied to the presenting head. The child was a very small one and was easily delivered, but on placing my hand on the abdomen to follow down the uterus I found another child in the womb. My friend examined and found the presentation to be the right shoulder. A little more chloroform was used and he had no difficulty in getting hold of a leg and turning, delivery being very easy. The placentæ were separate, both children were born alive and lived. There was a good deal of post-partum hæmorrhage, but with external kneading of the abdomen the uterus was kept well contracted and no further hæmorrhage occurred. The patient got on very well until about the twelfth day when she complained of pain in the left groin and calf. Her temperature was 102° F. and the leg began to swell. I treated the white leg with the general routine treatment and it got all right. Both children died in convulsions, one three weeks after birth and the other a month. I am, Sirs, yours faithfully,

Ernest E. Crowther, L R.C.P., L R C.S. Edin., &c.
Luddenden, May 10th, 1904.

LIFE IN CRYSTALS.

To the Editors of The Lancet.

Sirs,—Acting on the principle expressed by the motto which heads your correspondence columns you recently afforded to Dr. H. Charlton Bastian an opportunity of expounding views on heterogenesis to which exception is very generally taken in scientific circles. In the same spirit may I call attention to an article by M. F. di Brazza and M. P. Pirenne in the *Revue Scientifique* of April 22nd, entitled "La Vie dans les Cristaux" which may be regarded as indirectly supplying some measure of confirmation to Dr. Bastian's opinions? The article referred to consists mainly of an exposition of the theories of M von Schrön, director of the pathological institute of the University of Naples, as to the origin and mode of development of crystals, and the writers are led to the conclusion that they have to do with undoubted instances of the spontaneous generation of living things from aggregates of molecules. The living things are, it must be admitted, crystals, but M. von Schrön is convinced that young and growing crystals are alive though old ones may have ceased to be so, and he traces a marked analogy between crystals and the cells of animals and plants. He has watched the formation of crystals under a magnification of 800,000 and he describes the appearance from an initial "pétroplasme," which is comparable with the "bioplasm" of animals and plants, of "petro-cellules" with nuclei containing a nuclear network. The petro-cellules give rise to crystals and the young crystals have the power of locomotion and, like the lowest zoological or botanical types, can reproduce their kind by division, gemmation, and endogeny. The young crystal has also its special pathology and may exhibit hereditary maladies in the way of bifurcation, torsion, or erosion. M. von Schrön suggests that Redi's dictum, *Omne vivum ex ovo*, and Virchow's *Omnis cellula e cellula* call for revision and he proposes the formula *Omne vivum e molecula* as more in accordance with the facts of the case. If these observations are verified the result can hardly fail to be curious and interesting. I am, Sirs, yours faithfully,

S.

THE CHOLERA AND ENTERIC FEVER EPIDEMICS AT HAMBURG.

To the Editors of The Lancet.

Sirs,—Dr. Reincke writes to correct some statements made in your leading article on the paper which he recently read to the Epidemiological Society. As these statements were evidently based on the description which I wrote when visiting Hamburg to investigate the causes of the cholera[1] perhaps I may offer some explanation. I then described Altona as being built on a hill and that it juts out in a somewhat startling manner, so that it may well be compared to a rock or a cliff. I confess that I did not investigate the exact composition of the subsoil of this hill but Dr. Reincke now informs you that it consists of North German geest, the same soil as that of the greater part of Hamburg. If reference is made to the map published with my article on Hamburg it will be seen that "the greater part of Hamburg" did not suffer half as much as the smaller part of Hamburg which is built on damp subsoil, marshy land recently redeemed from the river. Thus the topographical differences produced their effect, not only in regard to Altona as compared with Hamburg, but within the boundaries of Hamburg itself. The sanitary authorities, who showed me every courtesy, and I am pleased after the lapse of so many years to have another opportunity of again publicly thanking them, assured me that there was a low-lying and damp part of Altona where a good many cases of cholera had occurred. Whatever the composition of the subsoil these low lying districts did suffer the most, but they are also the poorest and the most overcrowded and it is not one cause but many causes that bring about such an epidemic. Therefore, and in spite of the great importance of water-supply, these other causes must be carefully considered.

I am, Sirs, yours faithfully,

London, May 7th, 1904. Your Special Correspondent.

THE GERMAN SURGICAL CONGRESS.[1]

(From our Berlin Correspondent.)

(*Continued from p. 1309*)

Operations on the Bones and Joints.

Dr. **Samter** (Königsberg) recommended in old dislocations of the jaw the performance of operative reposition instead of by resection.

Professor **Riedel** (Jena) said that subcutaneous catgut sutures yielded the best results in recent and old fractures of the patella. He showed some patients who had been treated in this way and had excellent use of the knee joint.

Dr. **Bockenheimer** (Berlin) showed a patient whose scapula had been removed and had afterwards undergone regeneration. For this to take place it was, of course, essential that the periosteum should be preserved. One of Dr. Bockenheimer's patients continued to follow his employment as an acrobat.

Dr. **Konig** (Berlin) recommended suture of fractured bones, especially of the epiphysis; this proceeding was very valuable in cases of fracture-dislocation. He had used this method in 11 cases, one being that of a patient with several fractures. One patient had an intracapsular fracture of the neck of the femur in which accurate suture of the capsule was essential. The results were very satisfactory.

Dr. **Samter** mentioned a case of pseudo arthrosis of the tibia where he had obtained consolidation by implanting a large periosteal flap and a piece of bone from the femur.

Professor **von Bramann** (Halle) said that in a case of sarcoma of the humerus he had replaced the diaphysis by a sterilised piece of bone from the tibia six inches in length, the result being that complete consolidation was obtained.

Dr. **Neuber** (Kiel) said that a piece of wood, which, of course, must be removed after a sufficient formation of bone had taken place, was likewise efficacious.

Operations on the Kidney.

Professor **Kümmell** (Hamburg) discussed tuberculosis of the kidneys. He recommended early operation as serious lesions of the kidney might sometimes be attended by only slight symptoms. In every case of old cystitis, especially in women, the urine should be examined as to the presence of tubercle bacilli; when those bacilli were present a radical operation should be performed as soon as possible; the results were generally good. Of 260 operations performed by him 48 were for tuberculosis.

Professor **Kronlein** (Zürich) confirmed Professor Kummell's statement that tuberculosis of the kidneys was more frequent in women than in men. Since 1890 he had operated on 34 patients of whom 12 had no other symptoms of tuberculosis whilst in 32 there were multiple localisations of the disease. He was of opinion that an ascending form taking its origin from the bladder did not exist but that infection always occurred by way of the circulation.

Professor **Kuster** (Marburg) said that he had observed that the disease was more frequent in men than in women. Tubercle bacilli were not always present in the urine nor was their presence a sure symptom of renal tuberculosis.

Dr. **Steinthal** (Stuttgart) reported that he had once operated in two stages At the first operation one of the ureters was tied and when by this proceeding the healthy state of one kidney was ascertained the other was removed by a second operation.

Appendicitis.

Dr. **von Büngner** (Hanau) read a paper on the size, structure, and shape of the appendix and discussed the methods available in the different forms of appendicitis. He distinguished an acute and a chronic form with many subdivisions. He generally insisted on early operation.

Dr. **Lauenstein** (Hamburg) said that he dissented from the view held by Dr. Büngner to the effect that there existed so many forms of appendicitis showing distinct symptoms. His classification of appendicitis was into acute and sub-acute or chronic with or without perforation. When the cases were operated on early there was no perforation.

---

[1] For this report we wish to tender our thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our correspondent.—Ed. L.

Dr. **KAREWSKI** (Berlin) expressed the opinion that in acute cases an operation should be performed at once when medical treatment did not completely relieve the symptoms. Operation in the interval should also not be too long postponed.

Professor **SONNENBURG** (Berlin) insisted on the fact that opinions as to the necessity of an operation have naturally changed because the clinical material itself has changed on account of patients now presenting themselves at an earlier stage of the disease than formerly. The very acute forms of appendicitis with septic symptoms and the early stages of subacute peritonitis were now better known and surgical aid was thus sought at once. Professor Sonnenburg, however, did not advise early operation when the suppuration had no tendency to spread and when the symptoms nearly disappeared after some days.

Dr. **FEDERMANN** (Berlin) reported six cases of ileus following operation for appendicitis. The patients' temperature was normal; the pulse also was normal at first and only became frequent in an advanced stage. The number of leucocytes was normal or even subnormal and only increased when an abscess developed.

Hernia.

Professor **MADELUNG** read a paper on very large herniæ which frequently occurred after operations for strangulation or after unsuccessful radical operations. These cases were seldom improved by a simple operation; resection of the prolapsed portion of the intestine and suture were necessary.

Professor **HELFERICH** (Kiel) called attention to the fact that shock might ensue on the reposition of enormous herniæ.

Dr. **KAUSCH** (Breslau) expressed the opinion that these herniæ ought always to be operated on while the patient's general state was still satisfactory. Previously to the operation the patient must be confined to bed for several days with his pelvis raised so that the protruding intestines might tend to fall back.

Professsor **BRAUN** (Göttingen) said that these herniæ might be considerably reduced in size by elastic compression.

Dr. **BRODNITZ** (Frankfort) said that he had resumed the old method of Schwalbe—namely, the treatment of herniæ by injections of alcohol into the sac; he had treated 73 patients in that way of whom 45 had since been observed for more than six months. He found that of these 45 cases 19 were serious and four had relapses; ten milder cases and 16 herniæ in children were completely cured.

Operations on the Bladder.

Professor **REHN** (Frankfort) reported recent observations on growths of the bladder in workmen employed in aniline factories. A report of such cases had been already given by him at the congress last year. He proposed a collective investigation of the matter, the number of his own observations now being 23; five were papillomata, of which two afterwards degenerated into malignant growths; the others were originally sarcoma or cancer. The prognosis was very bad.

Dr. **SCHWERIN** (Hoechst) surgeon to the Hoechster Farbwerke, said that his attempts to produce such growths in animals by adding aniline to their food had failed; in the human subject the development of these tumours was very slow.

Dr. **STRAUSS** (Frankfort) said that he had once operated on a large benign fibroma of the bladder with a small peduncle; besides that fibroma there was a small indurated growth which was ascertained to be a cancer.

Professor **KRASKE** (Freiburg) mentioned some rare cases of vesical growths—namely, a myoma which was cured by partial excision, and an ulcerated gumma cured by anti-syphilitic treatment.

Dr. **PAGENSTECHER** (Wiesbaden) spoke on malformations of the bladder such as the bladder of hour-glass shape; the double bladder, each loculus containing one ureter and associated as a rule with other deformities; and diverticula of the bladder, cases of which last abnormality he had had under his own care.

Intraspinal Injections of Cocaine.

Dr. **KLAPP** read a paper on experiments made on animals for the purpose of preventing the rapid absorption of the fluid in intraspinal injections of cocaine. He found the action of adrenalin to be very unsatisfactory, whilst mucilaginous, oleaginous, and gelatinous solutions or emulsions were better.

At the general meeting of the German Surgical Association Professor **KRÖNLEIN** of Zürich was elected president of the next congress.

LATIN-AMERICAN MEDICAL CONGRESS AT BUENOS AYRES.

(FROM OUR SPECIAL CORRESPONDENT.)

[OUR Special Correspondent sent us photographs of the exhibition building at Buenos Ayres, of the building of the Faculty of Medicine, and of the San Roque and Isolation Hospitals, which were published with a preliminary note in our issue of April 23rd, p. 1155.]

IMPORTANT DEBATE ON YELLOW FEVER.

The Second International (Latin-American) Medical Congress was opened at Buenos Ayres with great *éclat* by President Roca in person. The inaugural ceremony took place in the Opera House, a handsome building, which was packed on the occasion, some 2000 people being present. On the stage, which was carpeted and artistically decorated with flowers and evergreens, were the President of the Republic, the Ministers of Public Instruction and Foreign Affairs, the members of the organising committee, the press, and the foreign delegates, numbering over 40, from the different South American republics and also from Mexico and Cuba. After the usual formalities had been gone through the foreign delegates in turn spoke for their respective Governments and each vied with the other in eulogy of the country, the great and beautiful city, and the energy displayed by the organising committee—a display of oratory well worth listening to. As is usual in Latin countries all were in full evening dress and white tie although the meeting was at 3 o'clock in the afternoon.

In the evening at 9 o'clock of the same day the Exhibition of Hygiene, which is being held in connexion with the Congress, was officially inaugurated and promises to be not the least interesting part of the Congress. The installations of the exhibition not being all completed it is not yet possible to give an exact and full description, but I may say that the display made by the Army Service Corps (*Sanidad Militar*) is most complete and very interesting and I doubt if in any European capital this department would be better represented. Many of the things are made by Lefévre of Paris, notably a cart filter with a capacity of 600 litres. At the back of the cart is the filtering apparatus (asbestos and charcoal) and a long inch hose conveys the water from any well or lake or puddle by means of a pneumatic pump to the filter from which the water issues perfectly clear and is conveyed by another smaller hose to the tank which occupies the rest of the cart which is drawn by two horses. I was much struck by the ease and rapidity with which the water was obtained and filtered. A fine portable camp oven for baking bread made in sections like a collapsable boat also drew my attention. Novelties in the shape of saddles for cargo mules, stretchers, and portable sterilisers for surgical instruments also call for notice. Some very creditable work was also apparent in aseptic furniture for hospital operating theatres and consulting rooms and there were some very fair specimens of surgical instruments all manufactured in Buenos Ayres. With one or two exceptions British manufacturers are conspicuous by their absence with regard to sanitary fittings, furniture, surgical instruments, and the like, but Messrs. Allen and Hanburys have a good show of infant foods and pharmaceutical preparations; Messrs. Brand and Co. and the Sanitas Co. are also represented but not fully. The place simply teems with French and German pharmaceutical specialities, especially French, while the show of mineral waters is a good one, "Taunus," "Kristalz," and "Birresbora" being all well represented.

Turning to the Medical Congress itself the most important paper read as yet (the Congress is still proceeding) is one on the International Prophylaxis of Yellow Fever, by Dr. J. B. Lacerda and Dr. Azevêdo Sodré of Rio Janeiro, Brazil, and the following are their conclusions: 1. Yellow fever is transmitted by means of the mosquito stegomyia fasciata which infects by the blood sucked from a yellow fever patient during the first three days of the disease. 2. The prophylaxis of yellow fever should tend to protect patients against the bites of mosquitoes and prevent the latter when infected from biting healthy persons. 3. All the old prophylactic measures such as quarantine, disinfections, cordons sanitaires, obligatory isolations, &c., should be abolished as illusory, inefficacious, and prejudicial.

These conclusions are also supported by Dr. William Dolz y Arango of Cuba, and Dr. Sodré proved that, working on the above lines, they are in a position to state that yellow fever had almost disappeared from Rio Janeiro. So much enthusiasm was provoked by these assertions that the Congress there and then resolved to send congratulatory telegrams to Dr. Octavio Cruz, chief of the sanitary service of Rio, and to Dr. Agramante and Dr. Carrol of the United States for their work in connexion with yellow fever. The contrary side was taken by Dr. Penna, chief of the isolation hospitals in Buenos Ayres, who sustained the following propositions: 1. The results of the studies of Dr. Sanarelli on the etiology and pathogeny of yellow fever have not suffered the slightest modification and may be considered at the present time as perfectly established. 2 These investigations have been confirmed in France, Italy, Brazil, and in the Argentine. 3. The conclusions arrived at by the United States military committee that the mosquito stegomyia fasciata serves as intermediate host between the yellow fever patient and the healthy individual have not been demonstrated and lack sufficient proof. 4. The counter proof of specific prophylaxis made in Cuba and San Paulo (Brazil) by destruction of the specific mosquito is not conclusive (insufficient). 5 The Havana committee has not proved that the disease transmitted experimentally by the mosquito is really yellow fever and the same applies to the French committee. 6. The prophylaxis of yellow fever should be conducted on the old system of disinfection and isolation. 7. International prophylaxis of yellow fever should suppress all measures tending to interrupt free commercial and individual traffic. 8. If it be true that the transmission of yellow fever is made by a mosquito of a certain species and that the statistics of the results obtained by artificial transmission of yellow fever are also true, then the means adopted for prophylaxis should not be "death to the mosquito" but preservation of these providential beings destined to act in the [illegible] [illegible]isers" exactly as we preserve an [illegible]

The last conclusion is [illegible], many speeches were made for and against, but no vote was taken as the subject possibly may be discussed afresh. Some good work was done in other sections but I must postpone the mention of these for a later date.

Buenos Ayres.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Cancer Research.

Dr. A. S. F. Grünbaum, the director of the Liverpool cancer research, has issued his report of the first year's work of investigation for the discovery, if possible, of the causes and cure of cancer. The plan of work adopted was (*a*) therapeutical and (*b*) experimental. The cytolytic milk of a cow and subsequently, when it yielded no more milk, its serum were tried. It was expected that it would have effect only on cancer of the breast but it was tried also on two cases of cancer of the stomach and one of the rectum. In one case of cancer of the stomach the milk was taken constantly until death; the other two patients did not continue to send for it so that their subsequent history is not known. Of two cases of cancer of the breast in one the disease is apparently arrested; the other, in which the disease was too far advanced, died. Three cases of uterine cancer are being treated with the serum from a horse; they all show objective signs of improvement. It is, of course, obvious that while surgical interference is considered the most hopeful treatment any new method tried only on cases beyond surgical skill will be severely handicapped. Of the value of the x rays as a curative agent in certain cases there can be no doubt but at the present moment the clinical and pathological characteristics of such cases are not defined and require minute investigation. Experimental work has been directed towards the causes of cancer. Until these are known very little can be done towards its cure and practically nothing towards its prevention. If once a strain of human cancer can be experimentally secured and continued the goal will be appreciably nearer. In carrying on the work the developmental and the parasitic hypotheses have consequently been kept in view. The recent additional evidence obtained by the London observers towards the germinal theory raises the hope that a comparatively simple physiological cure may be possible when it is remembered by what simple means experimental embryologists are able to alter the development of germinal cells. The occurrence of malignant disease in animals also came under investigation. A number of tumours from the human body were received in response to appeals made by Dr. Grünbaum to his professional brethren for specimens: about 57 per cent. came from the Liverpool Royal Infirmary, 16 per cent. from the London Hospital, 1 per cent. from the Royal Southern Hospital, and 26 per cent. from outside sources. Several tumours, mostly malignant, from animals have been received and examined; they include specimens from the horse, the cow, the sheep, the dog, the pig, the cat, the mouse, and the trout. The report practically includes only nine month's work to Feb. 1st, 1904, as the rooms in the laboratory of experimental medicine at the University of Liverpool were not ready until April, 1903.

The Roentgen Rays Department at the Royal Southern Hospital.

Through the liberality of Mr. John W. Hughes the x-ray room at the Royal Southern Hospital has been enlarged and fully equipped with the most up-to-date scientific apparatus. A few days since the new room was formally opened by Mrs. Hughes, the wife of the donor, in the presence of the honorary medical staff and several members of the general committee. Immediately afterwards Mr. C. Thurstan Holland, the honorary medical officer of the x-ray department, gave a demonstration on radium to an appreciative audience.

Health of Liverpool.

The death-rate for the past week was 22·3 per 1000. Three cases of small-pox were reported during the past week. There are 320 cases of scarlet fever in the corporation hospitals.

Death of Alderman John Lawrence, J.P.

By the death of Alderman John Lawrence the medical profession of Liverpool has lost a warm friend. He was a man of great abilities for business and public affairs and was especially interested in hospital administration. He was a prominent member of the committee of the Royal Infirmary since the year 1881; he was also a member of the council of the University of Liverpool as a civic representative. During the rebuilding of the Royal Infirmary his advice on legal matters, especially in reference to the purchase and the acquisition of neighbouring property, was invaluable. He also took a great interest in the subject of the renewal of the lease of the Medical Institution buildings, which has nearly run out and which is now a source of much anxiety to the trustees of the institution. At a general meeting of the society two months ago, at which he was specially invited to be present, he strongly expressed the opinion that as the objects of the institution were for the cultivation of medicine, surgery, and the collateral branches of science, thus tending to benefit society in general, a nominal fine ought to meet the circumstances of the case. His help was looked forward to when the matter would again come before the estate committee of the city council but it was decreed otherwise. He was a man of wide culture and possessed a charm of manner which made him a general favourite. His death occurred in pathetic circumstances, the intelligence of which came as a great shock to his numerous medical friends and others. He left Liverpool on March 31st, not specially ailing but in the hope that a trip to the Mediterranean would be of benefit after having somewhat overworked. He visited Constantinople, Smyrna, and Athens but, unfortunately, when nearing Gibraltar developed pneumonia, to which he succumbed in two days. He passed away on Sunday, April 24th, and was buried at sea on the following day. Mr. Lawrence, who was a solicitor, was brother-in law of Mr. T. Pickering Pick, consulting surgeon to St George's Hospital, London, and inspector of anatomy for England and Wales.

Liverpool Baths and Washhouses: Opening of a New Bath.

The new public bath in Lister Drive was formally opened on May 2nd. The building is a very imposing one. The style of architecture is Free Renaissance and has a very pleasing effect. After passing the turnstile the visitor finds himself in a very commodious entrance hall, from which there is direct access to the several sections and classes of baths which are all situated on one floor level. Each section has its waiting and cooling rooms. The first-class accommodation provides for eight private baths, slippers, sprays, Russian and vapour baths, and a swimming bath 75 feet by 35 feet, with dressing accommodation for from 75 to 100 bathers. This bath is designed for an entertainment bath but for the present the necessary spectators' gallery has been omitted. This feature can be added later. The ladies' section is capable of accommodating six bathers. Space has been reserved for the construction of a ladies' swimming bath when the demand justifies such a provision. A large bicycle stable is provided for the storage of bathers' bicycles. There is also a large room for swimming-club meetings. The administrative department includes a power-driven laundry and complete installation of up-to-date heating appliances both for atmospheric and water heating. The whole of the baths are top-lighted. The artificial lighting is electric, the current being supplied from the corporation mains. The ventilation is natural. The construction of the building is fire-proof. The interior of the walls is faced with enamelled bricks and tiles. The water-supply is from the corporation fresh-water mains, and by the coöperation of the water and the electric-power and lighting committees the baths committee has been enabled to make arrangements for the supply of fresh water for the swimming baths to be heated on its way to the baths in the following manner. A special supply of water is taken from the corporation main and is conducted in pipes to the electric generating section adjoining the baths, where it is passed through a specially designed heater placed in one of the exhaust steam mains of the station. The water heated to a suitable temperature for bathing purposes is then conveyed in pipes to the baths. In testing the heater it was found capable of heating 25,000 gallons of water per hour, raising the temperature from 43° to 73° F. This can be done without in any way affecting the water and electric-lighting committee's revenue, whilst it means a saving of at least £140 per annum to the baths committee. The total cost of the establishment of the baths is £24,000.

The Royal College of Physicians of London.

Dr. T. R. Bradshaw, honorary physician to the Royal Infirmary and lecturer on clinical medicine at the University of Liverpool, has been elected to the Fellowship of the Royal College of Physicians of London.

May 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Poor-law Conference at Malvern.

THE thirty-fifth annual conference of delegates from the 82 unions in the West Midland registration district was held at Malvern on May 2nd and 3rd. The area included in this registration district comprises the counties of Gloucester, Hereford, Salop, Stafford, Warwick, and Worcester. A very instructive discussion was introduced by Mr. J. D. Birchall of the Gloucester board of guardians upon "boarding out." He compared the advantages to the children themselves as well as to the ratepayers of placing children in scattered homes, in cottage homes, and of boarding them out in families both within the union to which the child is chargeable and in other unions. He emphatically recommended the adoption of the last-named course—namely, the placing of children "beyond the union" and deplored the fact that the number of children thus dealt with in 1900 being 1910 in 1903 it had fallen to 1674 although the total number of children chargeable to the unions had increased between the two dates from 57,453 to 61,993. There was a consensus of opinion among those who took part in the discussion that the children should not be kept in the workhouse proper but there was not the same unanimity with regard to placing them in groups in cottage homes or in scattered houses and boarding them out singly. Mr. E. B. Wethered, Poor-law inspector of the Local Government Board, said that everything depended upon proper supervision. He declared that the boarding-out system had worked very well at Bristol and that since the children had been removed from the workhouse they had developed both mentally and physically. Miss Mason, who is also a Poor-law inspector of the Local Government Board, agreed with Mr. Wethered that there was a great difficulty in finding suitable homes in which to place children. At the second day's meeting of the conference Mr. Geoffrey Drage read a paper upon Training Ships for Poor-law Boys. He pointed out that while in 1857 there were 97,000 British subjects employed in the mercantile marine and in 1899 there were 60,000 in 1901 there were only 44,500, and he suggested that boards of guardians by sending boys to a training ship would be doing the best thing possible for the boys and at the same time would be contributing to the nation's prosperity and safety.

Disinfection after Death from Phthisis.

Now that phthisis is recognised as an infectious disease it is probable that the keepers of lodging houses will more frequently exact payment for the disinfection of rooms occupied by phthisical patients. Such a claim was unsuccessfully defended in the Cardiff county court on May 5th. A lady who was suffering from phthisis occupied with her companion certain lodgings in Cardiff during the whole of last November and died at the end of that month. The proprietor of the lodgings claimed £50 from the husband of the patient as damages said to have been sustained owing to the occupation of the lodgings by his wife and to her subsequent death. Nearly half of this sum was for the rent of rooms which it was alleged certain persons refused to hire when they heard the cause of the previous lodger's death. The remainder was for the wear and tear of the house at the time of the funeral and for the value of bedding and other articles which had been destroyed. The county-court judge gave judgment in favour of the lodging-house keeper for £25 but would not entertain the claim for loss of rent. A somewhat similar case has been previously reported[1] where the cost of disinfecting rooms occupied by a consumptive person in a hotel was recovered in a county court. In this instance the judge held that on the evidence of the medical officer of health consumption is an infectious disease and that it would be dangerous to let the rooms again without disinfection. He did not, however, allow the claim made for damages in addition to the cost of disinfection.

Damages against a Quack Company.

A commercial traveller obtained £20 as damages in the Cardiff county court on May 5th against the Good Health Alliance Company. He purchased two "foot drafts," a form of plaster which it was said would relieve rheumatism but he contended that owing to the irritation which they set up on the soles of his feet where they were applied he was unable to follow his employment. Mr. Frederick Buckham, who attended him, ridiculed the suggestion of the defendant company that the "foot drafts" drew uric acid out of the system through the pores of the feet, but according to the newspaper report of the case Dr. Boyd, who was described as a London consulting physician, said that a good deal of the uric acid could be expelled from the body through the pores of the skin and that was what the plasters did. The county-court judge said that the company was liable for damages as the plaintiff had not been warned in any way as to the effect which the plaster might have.

Tramps and Small-pox.

The Leominster board of guardians recently adopted a motion expressing the opinion that it is urgently necessary to pass through Parliament a short Bill compelling all tramps to be vaccinated if they cannot produce evidence of recent vaccination. During some months of last year the public vaccinator was instructed to offer vaccination to all tramps who passed through the Leominster workhouse and in this way a great deal of good work was done. The board becoming alarmed at the cost involved the practice was suddenly dropped.

Royal Mineral Water Hospital, Bath.

At the annual court of governors of the Royal Mineral Water Hospital, Bath, which was held on May 2nd, it was stated that the hospital was closed for a few weeks during 1903 in consequence of a slight outbreak of small-pox in the town. The hospital, which was incorporated in

---

[1] Law Times, 1899, vol. cvii., p. 101.

1737, contains 165 beds and there were admitted for treatment last year 1163 patients, of whom 1027 were discharged during the year; of the latter number 84 were cured, 871 were much relieved, and three died; the remainder left for various reasons. The expenditure incurred during the year was £5343, or £444 in excess of the income.

Swansea Hospital.

Among many other charitable bequests of the late Mr. William Williams of Swansea is a munificent one of £2000 to found and to maintain a bed in the Swansea General Hospital. Dr. J. Arnallt Jones, medical officer of health of Aberavon, is a son-in-law of Mr. Williams.

The Vaccination Acts.

At the meeting of the Exeter guardians held on May 3rd a communication was read from the Reading union asking support to a petition to Parliament for the repeal of the Vaccination Acts and the rejection of the Vaccination Bill of 1904 on the ground that vaccination was dangerous to life and limb and useless to prevent the infection of small-pox. The Exeter guardians, however, decided to take no action in the matter.

May 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

General Council of the University of Edinburgh.

THE statutory half-yearly meeting of this body was held on May 4th. There were no matters of distinctively medical interest before the meeting. A committee was appointed to watch the progress of the Education Bill and a discussion took place on the merits of modern languages.

Lunacy in Scotland.

The annual report by the General Board of Commissioners in Lunacy for Scotland, which has just been issued, states that on Jan. 1st, 1904, there were in Scotland 16,894 insane persons under official observation. This number included inmates of schools for imbecile children and of the lunatic department of Perth General Prison. Of the total number, 2532 were maintained from private sources, 14,309 by parochial rates, and 53 at the expense of the State. The total showed an increase of 236 over the numbers of the previous year. When the Commissioners first took up office on Jan. 1st, 1858, the total number of lunatics officially known had been 5824, or 11,070 less than the numbers reported on Jan. 1st, 1904. The numbers of private patients in asylums had increased during the year by 111 and in private dwellings had decreased by two, an increase of 109 in all. The number of pauper patients in establishments had increased during the year by 80. This figure did not include inmates of training schools. As, however, the average annual increase of pauper patients in establishments had been 293 during the past ten years the increase for last year was 213 below the average. The number of pauper lunatics in private dwellings had increased during the last ten years from 2566 to 2658. Of registered lunacy as a whole the increase of 205 was the smallest increase recorded since 1891. Of the total increase of 205, 191 rose from an increase in the number in establishments and of this number 80 were pauper patients. This increase in pauper patients was the smallest that had occurred during the past 19 years. 16 counties show a total increase of 178 and the remaining 17 counties a total decrease of 98. The most prominent contribution to the increase was the county of Edinburgh with 48, or 27 per cent. of the whole. Inverness, Ross, and Sutherland showed together an increase of 41, or 23 per cent. of the whole. Aberdeen and Renfrew showed an increase of 29, or 17 per cent.; while Forfar with a growing population showed 21 fewer than last year. Lanark, Linlithgow, Dumbarton, Selkirk, as well as Caithness, Orkney, and Shetland, all showed a decrease. The number of pauper lunatics in establishments now amounted to 249 per 100,000 of the population, as against 250 per 100,000 in 1892. 21 years had elapsed since a similar fall had been recorded. It might be merely a passing phenomenon but it also possibly might be an indication that pauper lunacy, which had lately been so rapidly increasing, was at last reaching a point beyond which it would not materially rise.

University of Glasgow Court.

At a meeting of the University of Glasgow Court held at Gilmorehill on May 5th, Principal Story presiding, the finance committee reported that it had agreed to purchase from Mr. Alexander Stenhouse certain property in University Avenue, consisting of dwelling houses and shops with hall adjoining, at the price of £3800, subject to the court granting the vendor a lease of the shops for four years from Martinmas next. The report was adopted. This property is at present partly occupied by the Western Medical School. Lord Kelvin, who was recently appointed Chancellor of the University in room of the late Earl of Stair, has nominated Mr. Henry Gordon of Aikenhead as his representative on the University of Glasgow Court.

Annual Meeting of the Aberdeen District Registered Plumbers.

The annual meeting of the Aberdeen, Kincardine, and Banff district plumbers, registered by the National Registration of Plumbers, was held on May 4th in Robert Gordon's College, Aberdeen, Professor Matthew Hay, president, being in the chair. There was a good attendance. The fourteenth annual report submitted by the council stated that the plumbing classes carried on at Robert Gordon's College by Mr. W. A. Watt and Mr. A. Forbes, members of the council, continued to do excellent work, and the instruction and training which they afforded must have an important bearing on the qualifications of young plumbers who had the foresight to attend them during their apprenticeship. The number of students in attendance during the session was 43. The classes were arranged in three different grades of proficiency. A special feature was instruction in "lead burning"—a part of plumbing work hitherto confined to a very small section of the craft. Ex-Bailie Pyper had kindly renewed his generous donation of prizes, but the awards would not be announced till the end of the session. A balance of £15 1s. 6d. remained in hand after paying all accounts of the registration. Professor Hay commented on the satisfactory state of affairs and moved the adoption of the report. Councillor Robertson, vice-president, seconded the motion and the report was unanimously adopted. Both of these gentlemen referred to the Plumbers' Registration Bill and hoped that at no distant date they would see compulsory registration of plumbers. The following motion was proposed by Mr. John Clarke, lecturer on education at the University of Aberdeen, and was unanimously passed:—

> That the annual meeting [illegible]
> and district council for the [illegible]
> its emphatic opinion that [illegible]
> [illegible] economy, and that [illegible]
> Members of Parliament.

Tragic Death of a Stonehaven Medical Man.

The body of Dr. James Gordon of Stonehaven was found by two lads on May 8th suspended by a rope from a tree in a wood at Carsegownie Muir, about five miles from Forfar. Dr. Gordon succeeded to the late Dr. W. B. Leslie's practice in Stonehaven some two years ago. He was a native of Aberdeen and graduated with distinction at the University of Aberdeen. Deceased was, in not a few respects, a young man of great promise. After graduating he spent some time in practice in Aberdeenshire and in England and Wales, gradually building up a considerable reputation and sound knowledge of his profession. He was unmarried. The utmost sympathy is expressed for his father and mother and other relatives in the painful circumstances which have attended their sad bereavement.

May 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Meath Hospital and County Dublin Infirmary.

Dr. F. Conway Dwyer, professor of surgery, Royal College of Surgeons in Ireland, and surgeon to Jervis-street Hospital, has been appointed surgeon to the Meath Hospital and County Dublin Infirmary.

Cork-street Fever Hospital, Dublin.

The James Weir Nurses' Home in connexion with the

Cork-street Fever Hospital was opened on May 7th by his Excellency the Lord Lieutenant who delivered an interesting address on the occasion.

The Westmorland Lock Hospital, Dublin.

Mr. George E. P. Meldon has been appointed surgeon to the Westmorland Lock Hospital, in succession to Mr. M. A. Donnelly, recently deceased.

Sanitary State of Lisburn

The medical inspector of the Local Government Board (Dr. C. J. Clibborn) has drawn attention to the fact that no inspector of dairies, cowsheds, and milkshops has been appointed in Lisburn and the Local Government Board advises the Lisburn urban council to adopt a code of regulations for these places. It is reported that the sewerage of the town is defective and the Local Government Board advises steps to be taken to have maps of the sewerage system completed as soon as possible. A properly equipped disinfecting apparatus for use in the district is much needed as 66 cases of infectious disease (38 of scarlet fever, 10 of erysipelas, 16 of enteric fever, and two of diphtheria) were noted during the year.

Newry Fever Hospital.

At the annual meeting of the friends of this charity, held on May 6th, it was reported that the public subscriptions for the year were £310 9*s.* which with the county council grant of £400 make the annual income £710 9*s.* It takes £800 a year to maintain the hospital and at the end of 1903 there was a balance due to the bank of £182 17*s.* The county council proposes to reduce the grant per annum to £300 and when this is done, unless the public come forward with a generous and hearty support, the operations of this most deserving hospital will have to be curtailed largely.

Derry Eye, Ear, and Throat Hospital.

In place of the late Mr. E. Donaldson, former surgeon to this hospital, two appointments have been made—Dr. W. B. Hunter and Dr. G. K. Smiley.

Medical Relief in Coleraine Union.

Dr. H. S. Morrison, medical officer of Aghadowey dispensary district, has pointed out to the Coleraine guardians that in his district he had to attend on red ticket shopkeepers, tradesmen, dealers, road contractors, and millowners, and in two cases he had to attend on families who had a credit account in the bank of over £500. He had since the beginning of the year 250 new cases in the dispensary, many of which were unnecessary and would not have occurred if the people were farmers and had to pay. In reference to this the Local Government Board wrote that in order to enable the issuers of tickets to be in a position to judge whether applicants for medical relief are or are not "poor persons" the board of guardians may invite each of their medical officers to furnish in writing a scale of charges for attendance upon persons whose circumstances would not admit of their paying the medical man's usual fees. A special form of ticket, different in colour and wording from the medical relief tickets, has been adopted in some unions. It was decided by the Coleraine guardians to consider the question at a general meeting to be held in a fortnight.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Alternate Administration of Arsenic and of Sulphate of Quinine in Malaria.

AT the meeting of the Therapeutical Society held on April 27th M. Goldsmidt read a paper pointing out that arsenic would act favourably in cases of malaria where quinine failed and *vice versâ.* If, for instance, an attack of malarial fever would not yield to sulphate of quinine or to arsenic given in the second place it was almost sure to yield to a second dose of quinine given after the arsenic. The use of arsenic consecutively to sulphate of quinine had been found successful in intermittent affections other than malarial fever. More than 30 years ago M. Goldsmidt had cured in this way a young girl who suffered from intermittent attacks of torticollis. As regards the various preparations of arsenic he considered that arrhenal had *manifest* advantages over arsenious acid, especially from the point of view of its lesser degree of toxicity which rendered it easier to employ subcutaneously. But it remains to be seen whether the results obtained with arrhenal are better than those obtained with arsenious acid.

Antivenomous Sera.

M. Calmette of Lille, who has just been elected a corresponding member of the Institute, read an important paper on May 5th before the Academy of Medicine upon the above subject. As is well known, the discovery of antivenomous serum is due to M. Calmette. But on continuing his researches he found that the venoms of different serpents were not all of the same type. There are two main species to which all the others conform, cobra venom and viperine venom. The first is especially toxic, the second produces hæmorrhages. M. Calmette has succeeded in preparing one polyvalent serum which acts equally well in both kinds of poisoning. By studying the action of the neurotoxins which serpent venom contains upon the globules of the blood and upon gelatin M. Calmette has devised a method for standardising the toxicity of venom with accuracy.

Death of M. Duclaux.

M. Duclaux, the director of the Pasteur Institute, died on May 3rd from a seventh attack of apoplexy. M. Duclaux was foremost among men of science and his researches upon milk, amongst others, were a direct continuation of the work of his old master, Pasteur.

The Voices of Deaf-Mutes.

M. Marge has for some time past obtained remarkable results in the education of the voices of deaf-mutes by the use of sirens and tuning forks. In this way he makes the patients appreciate the sounds for the obtaining of the enunciation of which he has shown them how their lips and cheeks should be placed. On April 26th he gave a demonstration at the Academy of Medicine upon the pronunciation of the vowels. As a matter of fact, every vowel has more than one sound and hitherto patients have been taught the same method of emission for the "a" sound, whether short or long, or the "e" sound, whether mute or "é." By employing sirens in a new fashion and by accustoming the patient to sing a given note in unison with the siren until he mastered how to dispose his vocalising organs in conformity with the sound perfection has been nearly attained.

French Congress of Climatotherapy and Hygiene in Towns.

The first French Congress of Climatotherapy and Hygiene of Towns was held at Nice from April 4th to 9th, the subjects discussed being practically the same as stated in the preliminary announcement published in THE LANCET of Jan. 2nd, p. 44 Discussions were held and papers were read on April 5th, 6th, 7th, and 9th, the work beginning at 8 A.M. each day. Each afternoon, and the whole of April 8th, were occupied in excursions and the evenings were devoted to fêtes, receptions, or operatic performances. The Congress was in every respect a great success. The attendance exceeded 1000 and the arrangements were excellent not only with regard to the business of the sections but also in respect of the excursions and the various festivities. The bulk of the members were naturally Frenchmen, with whom there were a few Belgians, Italians, and Swedes. The British contingent was unexpectedly small, only two names of English medical men appearing on the list. Mr. S. Osborn, F.R.C.S., was present and Dr. I. Burney Yeo (London) read a paper entitled "Les Auxiliaires de la Climatothérapie."

Musical Expression in a Condition of Hypnosis.

A hypnotic subject named [illegible] has just been giving in public certain [illegible] rious and quite individual character. [illegible] who is obviously of a hysterical nature, possesses the property common to all persons like herself of being able vividly to express while in a state of hypnosis the emotions which correspond to auditory impressions which she receives. She recently gave an exhibition at the Théâtre des Mathurins before the Association of the Medical Press. When thrown into the hypnotic state by M. Paul Magnin, Madame Magdeleine, as soon as she heard the music, appeared to attune herself to the instrument and translated into terms of the most expressive mimicry the various symptoms which the music expressed. By impassioned gestures, by joyous dances, or by attitudes of sorrow she gave a picture of emotions which even professional actors were obliged to say were very remarkable. Selections from the works of Beethoven, Chopin, Massenet, and of Schumann, when played before her called forth on her part the most artistic interpretation. When, however, the pianist improvised so that Madame Magdeleine could not have known anything about the music her expression and the richness of her improvisation were just as good as when music which she might have known was played and this test obviously did away with all idea of trickery. When awakened from the hypnotic state she is an intelligent and amiable woman but one quite incapable of reproducing the same passion and emotions which she experiences while in the hypnotic state. After the *séance* Dr. Berillon, who was present, pointed out that such phenomena have been known in a general way for a long time past to hypnologists, but that Madame Magdeleine exhibited a receptivity altogether out of the ordinary for auditory impressions and was able to give expression to them in a most exceptional way which was both interesting and artistic.

May 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Epidemics and the German Red Cross Association.

RECENT legislation requires towns and rural districts to make certain arrangements in the event of epidemics occurring. For instance, the families of patients must be isolated in special premises and patients' clothing which it may have been found necessary to destroy must be replaced. Apparatus for disinfection must be provided and any loss or damage inflicted on individuals by processes of disinfection must be made good at the public expense. The smaller towns will obviously have some difficulty in complying with these requirements and it is therefore satisfactory that the German Red Cross Association, in return for an annual sum to be paid to it by the public authorities of the places concerned, has proposed to assume the duties imposed by the law on the smaller towns and rural districts. The system is, in fact, a kind of mutual insurance of the small communities against the expenses of epidemics. It is proposed that communities of fewer than 1000 inhabitants shall pay only 5 marks (i.e., 5*s.*) a year. As there are in Prussia 48,993 towns, villages, and districts of fewer than 1000 inhabitants and 3688 having from 1000 to 5000 inhabitants a considerable sum will evidently be collected every year in this way. Of this money a certain portion is to be spent every year in providing portable huts, tents, apparatus for disinfection, clothing, and other requisites which are to be kept in the stores of the association and conveyed when required to the places where epidemics have broken out. The committee of the association hopes to be able in a few years to meet all the wants of the rural towns, provided that a sufficient number of communities accept those proposals.

The Hygiene of Health Resorts

[illegible] of spas and health resorts and finally a series of definite recommendations was made, of which the following is an abstract. A sanitary commission ought to be formed in every spa and health resort. The notification of scarlet fever, measles, diphtheria, enteric fever, and phthisis ought to be made compulsory. In the smaller spas and health resorts, where there is no hospital, arrangements ought to be made with a hospital of the neighbourhood for the reception of patients, especially those suffering from contagious diseases. [illegible] premises for the isolation of [illegible] provided in every spa. The [illegible] hould be authorised to inspect [illegible] dwelling houses and places of [illegible] ng the bathing season [illegible] to be corrected. In [illegible] cf Colberg rightly observed that not only the spa but also the public had obligations to fulfil in the interests of the general welfare; he especially drew attention to the fact that parents took their children [illegible] whooping-cough to [illegible] en as a rule did not [illegible] go and were a source [illegible] they met there.

Blindness and Deaf-mutism.

The number of the blind has been continually decreasing in Prussia since 1871. According to the *Statistical Correspondence*, quoted in the *Vossische Zeitung*, there were 92·09 blind persons in each 100,000 of the population in 1871, 82·49 in 1880, and 61·04 in 1900. With respect to sex, the proportions of blind persons were 65·13 males and 58·56 females in each 100,000. Whilst in 1871 the number of blind females (11,759) exceeded that of the [illegible] ons were [illegible] d 11,504 [illegible] articulars [illegible] 1871 and 31,278 in 1900. Although their absolute number has increased the proportion of the deaf-mutes to the general population has somewhat decreased, being 97·51 in each 100,000 in the year 1871 and 90·73 in the year 1900. More than 50 per cent. (16,856) of the deaf mutes were able to work, upwards of 6000 being employed in agriculture and upwards of 5000 in various trades. It was rather remarkable that the decrease occurred only in the male sex, the females showing even a slight increase.

May 9th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Experiments on Feeding.

ON April 20th a paper was read before the National Academy of Sciences describing a series of experiments recently carried out by the Sheffield Scientific School of Yale to determine the amount of food necessary to sustain the human frame in good health. Professor Russell H. Chittenden, the director of the school, who conducted the experiments, read the paper. He said that three classes of men were experimented on—namely, several professors of the school, some students, and a squad of United States soldiers. There was a gradual reduction of meat and other proteid foods with little if any increase in starch and other foods in nearly all the tests. No fixed regimen was required in any case, the endeavour being to satisfy the appetite of each subject. At the end of the experiments, which lasted six months, the whole body of men who had been the subjects were in the best of health. Their weight in some cases was almost exactly the same as when the experiments were begun and in some slightly lower. The daily consumption of food was found at the close of the experiments to have been much less than the recognised standard and from a third to half as much as the average man eats.

Bellevue Hospital, New York City.

The inadequacy of the accommodation at Bellevue Hospital has been a subject of complaint for a considerable time and affairs have recently reached a climax. Owing to the inclement weather which has been experienced in New York city for the past few months the hospital has been greatly overcrowded, the consequence being that the work of the medical staff has become very heavy. At the present time three and sometimes four or five physicians are compelled to sleep in one room. As to the patients, according to Mr. Mabon, superintendent of the hospital, not only is every cot occupied but a large number of the inmates must sleep on mattresses placed on the floor. It is gratifying, therefore, that the plans for the new Bellevue Hospital to cover three city blocks are now on exhibition. The sum of $702,000 (£140,400) has been asked for from the New York City Board of Estimate for the first pavilion, and no considerable delay in proceeding with the work is expected.

The Discovery of Anæsthesia by Ether.

Mrs. Elizabeth Morton, the widow of Mr. W. T. G. Morton of Boston, Massachusetts, the American to whom is attributed the discovery of anæsthesia by ether, died on April 21st from pneumonia at the Hotel Martha, Washington. Mrs. Morton, whose maiden name was Whitman, was born in 1826 in Farmington, Connecticut, and was married to Mr. Morton in 1844. Soon after marriage her husband began that series of experiments which ended in the famous public demonstration that by the inhalation of ether vapour surgical operations could be rendered painless. It is a sad illustration of the proverbial ingratitude of republics that the American Government never admitted that Mrs. Morton had any claim on it, although the reports of six Congressional committees during her husband's lifetime had recommended that an appropriation of several hundred thousand dollars should be made in recognition of the value of ether anæsthesia during the Civil War.

The United States Commission to the Isthmus of Panama.

The United States Commission to the Isthmus of Panama was accompanied by Dr. Gorgas and Dr. Le Garde of the army, Dr. Ross of the navy, and Captain Gillette of the United States Engineer Corps, who are now engaged in making investigations of the various hospitals heretofore established by the French company and in looking into the general sanitary regulations which will be necessary. Mr. Parsons, one of the commissioners, who has recently returned to the United States, while acknowledging that the present death-rate on the isthmus is high, has expressed confidence that with a supply of good water furnished both to Colon and Panama and with a complete system of sewers, supported by proper sanitary regulations vigorously enforced, both of these cities can be made healthful places of residence.

April 30th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

A CASE of bubonic plague of a mild character has occurred in Sydney. It appears that the patient, a boy, had been employed at a produce store where rats had been dying in numbers and he had to remove their bodies. As rats on the premises were found to be plague-infected the mode of infection in this case seems clear. When cases of plague were found some time ago in Queensland the New South Wales authorities prohibited grain and fodder from Queensland from entering New South Wales. The Queensland Government protested that such prohibition was a violation of the regulations of the Venice Convention and an unfriendly act. Now that plague exists in New South Wales Queensland has retaliated by prohibiting produce from New South Wales. A fatal case of plague has occurred at Cairns, Queensland, in an aboriginal woman.

The Declining Birth-rate.

The Government statistician of Victoria, Mr. W. McLean, read a paper on the Declining Birth-rate in Australia at the last meeting of the Medical Society of Victoria. He stated that after a careful investigation he was unable to agree with Mr. Coghlan, the New South Wales statistician, that there was only one explanation of the decline—viz., the application of artificial checks to conception. Mr. McLean maintained that the decline was due mainly to natural causes. First of all he observed that the ordinary birth-rate per 1000 of the total population was untrustworthy in young communities. In the earlier years the population, owing to immigration, consisted mainly of men and women at the reproductive period of life. As time goes on the proportion of such to the actual population must diminish and with it the birth-rate. A more correct rate is the ratio of legitimate births to married women under 45 years of age. But even the correct rate, as estimated by Mr. McLean, showed a decline. One of the causes assigned by Mr. McLean is the cessation of immigration, the immigrants being specially selected and of a type likely to be prolific. The next cause, in Mr. McLean's opinion, is a low and declining infantile mortality. He quoted a number of figures from different countries showing *primâ-facie* evidence of the intimate connexion existing between the two events (birth-rate and infant mortality). This association, he said, cannot be regarded as fortuitous and the death of an infant under one year does not present any obstacle to conception of another child but nurture of the child does. It was then shown that in Victoria there had been a decline in infantile mortality and also in New South Wales. The infant mortality was also relatively low compared with some European states. In this connexion Mr. McLean takes exception to a statement made in this column in THE LANCET of Jan. 16th last, p. 200: "Not only is there a declining birth-rate but also an excessive infantile mortality in New South Wales." This assertion was made with reference to a recommendation of the health officer of Sydney for the purpose of trying to diminish "the excessive infantile mortality" in that city. The relative infantile mortality may be comparatively low and yet, because far from the lowest possible in a young country with relatively small population and a healthy climate, actually excessive. The Royal Commission on the birth-rate also inquired into the infantile mortality. It reports as follows:—

> The mean infantile mortality (i.e., the number of deaths of infants under one year of age in every 1000 children born) for a period of ten years, 1892 to 1901, in the Australian States and New Zealand, is as follows:—New South Wales, 110 6; Victoria, 109 0; South Australia, 106 0; Queensland, 103 2; West Australia, 146 1; Tasmania, 95 3; New Zealand, 81·4. The figures representing infantile mortality in New South Wales for each year, from 1864 to 1902, show that for the period of 29 years since 1874 the rate has been a fairly level one; for the ten years prior to 1874 the mean-rate was somewhat lower; and in the 40 years reviewed the infantile mortality has not increased. Infantile mortality in Sydney compares favourably with that in other large cities. The study we have made of the causes underlying infantile mortality has satisfied us that it is far higher than it would be if all were done that could be done and might reasonably be expected to be done to protect the new-born from the many risks to life to which their helplessness exposes them.

Mr. McLean also took exception to the following statement by Mr. P. E. Muskett in his work, "The Feeding and Management of Australian Infants in Health and Disease": "It is now nearly 14 years ago since I first called attention to the appalling infantile mortality obtaining in the different Australian States." Mr. McLean maintains that the Australian mortality is not appalling when compared with that of European States, Sweden and Norway excepted. He gives the rate for Great Britain as 15 and for Australia as 11 per 100 births. Saxony, the highest, is 28. In discussing the paper Dr. Barrett considered that to account for a low birth-rate as a consequence of a low death-rate was an inversion of cause and effect. With fewer children increased care was taken of those that were born. In Australia the death-rate had not dropped in proportion to the birth-rate.

Sale of Poisons and Patent Medicines.

Incidentally the Birth-rate Commission inquired into the sale of certain drugs and patent medicines and obtained a report from the Government analyst on 22 much advertised nostrums, nearly all of which were found to be dangerous to life unless used under proper advice. Careful consideration of the whole of the evidence regarding the Poisons Act leads the Commission to make the following recommendations:—

> 1. That the Act be amended so as to apply to the sale distribution, gift, or disposal o[illegible] e abortifacient. 2. That t[illegible] sale of patent medicines, [illegible] whether they contain poisons [illegible] which contain poison, if accurate formulæ of such articles be not printed or written plainly on the bottle, case, box, or wrapper immediately containing them, together with the name of the vendor.

The Balmain Hospital and its Honorary Medical Staff.

As stated last month, the board of the Balmain Hospital appointed as paid medical officer Dr. P. J. Kelly who had been ostracised by the New South Wales branch of the British Medical Association for accepting the position of medical officer to the Balmain United Friendly Societies' Dispensary. The honorary medical staff warned the hospital board that if Dr. Kelly was appointed the honorary staff would not work with him. At the meeting of the board on March 21st the staff announced that its members had decided to give a fortnight's notice of their intention to resign unless Dr. Kelly withdrew. At the board's meeting on March 27th the staff wrote tendering their resignations but stating that they would continue to act until arrangements could be made to relieve them. The resignations were accepted and applications were invited for the positions. The board placed on record its appreciation of the services rendered to the hospital by the late members of the honorary staff.

Women's Hospital, Sydney.

The report presented at the eighth annual meeting of the supporters of the Women's Hospital, Sydney, stated that at the last annual meeting it had been decided that the institution should amalgamate with the Benevolent Society of New South Wales upon a scheme which was recommended by the directors. Steps were taken in this direction and for a period of over three months the Women's Hospital was under the administration of the Benevolent Society. After the experience then gained it was found that the basis of agreement had evidently not been clearly understood by the authorities of the Benevolent Society and it was agreed that the Women's Hospital should withdraw from the amalgamation at the stage it had then reached. One of the advantages looked for in the proposed amalgamation had been the securing of an up-to-date hospital building. Failing the completion of those arrangements the matter had been seriously considered by the directors and they were determined to make special efforts during the coming year

to obtain funds from the public to purchase a suitable building. During the year 438 patients were treated by the indoor department, 412 were discharged, one died, and 25 remained in the hospital. There had been 272 births (143 males and 129 females). No less than 1692 patients had been treated by the outdoor department and there were 431 births. The average cost per bed was £51 16*s.* With reference to this hospital Dr. A. W. Munro, in an address to the Obstetric Nurses' Association, said that by the practice of the hospital the total mortality of childbirth in the State had been reduced by half. He also showed how in the ten years of the history of the institution just completed the scourge of puerpera
obstetric practice in
which fact was main
3891 cases were attended by officials of the institution in the ten years under review. In order that the practice of midwifery might attain its proper level he advocated the raising of the educational and social status of those who engaged in the art of obstetrics.

April 5th.

Obituary.

RICHARD SISLEY, M.D., M.R.C.P. LOND.,

LATE MEDICAL REGISTRAR, CURATOR OF THE MUSEUM, AND PATHOLOGIST TO ST. GEORGE'S HOSPITAL.

WE regret to announce the death at Florence of Dr. Richard Sisley, which occurred on Saturday last, May 7th.

Dr. Sisley was but little known in the medical profession, where he never took the position to which he had a right by his learning, originality, and industry—qualities of his which our connexion with him, as a member of our staff, enabled us to appreciate thoroughly. He was born at Godalming on August 4th, 1856. He came of an old Huguenot stock, his ancestors settling in Sussex and later in Surrey, after the Revocation of the Edict of Nantes, and following the occupation of millers. His mother was a Miss Webber, of Morchard Bishop, Devon. He was educated at Reading School and St. George's Hospital and as a student his individualities made him a marked man, for in methods of working, choice of recreation, and even in clothes he was a law to himself. And to such a height did his hatred of anything like conventionalism rise that he could not bring himself to pretend docility, however perfunctory, where his feelings were those of resistance—he justified in fact his Huguenot origin. Consequently he found it impossible to conform to the curriculum provided for him by his medical school, certain lecturers being so antipathetic to him that he was driven to obtain instruction in their subjects at other hospitals. Having duly become qualified he served his turn as house physician at St. George's Hospital, which office at that time, being necessarily preluded by the offices of assistant medical registrar and house physician to out-patients, implied a two years' residential appointment. As a resident he was quickly found by the hospital authorities to be an able man and a vigorous thinker, while his displayed prejudices and antipathies passed unnoticed because in the main they were so just and generous. Having taken the M.B. Lond. with honours in botany, chemistry, obstetrics, and medicine he went to Vienna and worked hard at practical pathology. On his return to England he was elected pathologist and curator of the museum at St. George's Hospital and later medical registrar. As medical registrar it was his business to examine and to make notes upon every case admitted to the medical wards and Sisley toiled enthusiastically in the splendid clinical field now at his disposal. In this appointment he will be remembered by several generations of students at St. George's Hospital because of his unvarying kindness to them as a coach. Sisley's generosity in respect of those who needed instruction, and especially of those to whom the fees of the usual coach were prohibitive, was literally unbounded. If a man showed a desire to learn, if he was "hard up," and if he was not a swaggering man or an untruthful man, Sisley would coach him gratuitously in the wards, the deadhouse, and at his private rooms until he could not help passing his examinations. In fact, all through his too short life, where he gave his service either as a duty to his views of generosity or out of affection to a friend, he gave it fully and without stint.

At the end of his term as medical registrar it was expected confidently by all his friends that Sisley, who had now taken his M.D. at London University and had also graduated in State Medicine, would be elected upon the staff of the hospital but the hospital authorities thought otherwise. They saw Sisley's difficult side as a colleague, they knew him as a man of firm opinions and uncompromising views, but they did not apparently see in him a strong and loyal man who would have worked ably and hard for the school, the charity, and his profession. He was twice passed over and having been made to feel that further candidature was useless he retired from the contest and to a great extent from the practice of his profession. At the same time his interests in medicine, and especially epidemiology, impelled him to continue at medical work, and in 1891 he produced an able and highly interesting monograph on the Influenza Epidemic of 1889–1890, clearly proving the contagious nature of the disease at a time when the theory of miasmatic origin was still generally received. Dr. H. Franklin Parsons's official report on the same epidemic, which was published almost simultaneously, went over much identical ground, and from the day of the issue of these two independent treatises the method of spread of influenza has never been in doubt. In 1892 he made an investigation into the epidemic of cholera then prevalent in Russia, which appeared partly in our columns and partly in those of *Public Health*, and upon his return he planned a riding tour through England with the idea of making discursive remarks upon the rural sanitary conditions of the country. The scheme came to nothing, partly because Sisley saw almost at once that the labour of such a survey, however superficial would be too much for one man, and partly because the archæology, customs, and folklore of the counties through which he first rode—Norfolk and Suffolk—appealed to him so vividly that his interests became diverted. From this time forth for the rest of his life, although until 1900 he always kept a *pied à terre* in London, he lived largely in the country, and wherever he lived his mental energy and curiosity impelled him to acquire first-hand knowledge. At Godalming he had a beautiful house and here he embarked largely but without profit upon market gardening; at Southwold he kept a boat and took a practical interest in fishing and was a Past Master of the Martyn Lodge of Freemasons, No. 1983, which meets at that town; and latterly, when he resided on the coast of North Devon, he started to breed Exmoor ponies.

Some eight years ago he began to write occasionally for THE LANCET, his articles being always marked by originality of phrase and love of accuracy. His quaint erudition, shown in his practical knowledge of fishing, of gardening, of forms of agriculture, of many local sanitary or insanitary customs, of cooking, of many departments of art, of ecclesiastical music and church ritual, made him able to review with justice books dealing with other than medical issues, and as a reviewer he was distinctly kind, having no finicking over-appreciation of a writer's style but an unerring eye for the value of his matter and for the care with which he had striven to remove sources of mistake. In 1897 he performed a great journalistic feat for us by making an exhaustive survey of the premises, stations, filters, and distributing methods of the water companies of London. That the purchase of the undertakings of the various metropolitan water companies by Government, by a Water Board, or by the London County Council (as sanitary authority over a great part of the district supplied) would form part of the approaching political programme we had felt assured, and we found in Dr. Sisley, who had studied the question historically and politically, an ideal writer, anxious to clear up as far as possible all the public doubts as to the position of these splendid monopolies. Day after day he visited the various stations of the companies whose officials extended to him every facility for inspecting and reporting upon their work. The articles ran serially in our columns for over a year, they bristled with figures, and were fully illustrated with maps and plans drawn under Sisley's directions; but despite the technical and occasionally contentious nature of much of the information, and despite the many critical eyes that must have watched them for errors either of statement or deduction, for practical purposes his words passed unchallenged. A Royal Commission and a Court of Arbitration have gone with care over the same ground since and have confirmed the scrupulous accuracy of his statements. The articles, with slight alterations, were published later by the Scientific Press in a book which constitutes a small but significant memorial of Sisley's determination, powers of observation, and passion for being exactly right.

Although the end of his life came abruptly his health, which in spite of his big frame and strenuous ways of living had never been good, had begun to fail for the last five years. While pathologist at St. George's Hospital a severe attack of diphtheria, contracted in the post-mortem room, was followed by paralysis and signs of cardiac failure. This was nearly 20 years ago and during most of the intervening period he seemed sound and vigorous and not, indeed, to be damaged permanently. But his habits of life and multifarious interests and pursuits induced in him great physical strain that was frequently followed by collapse, breathlessness, a little tendency to anæmia, and occasional attacks of bronchitis. This should have warned him to be more sedentary, but his recovery always seemed complete and it was always followed by further long sailing expeditions in an open boat, long drives across the countryside in a dogcart, or long tramps over the Surrey hills or the Suffolk flats, and in each case his expeditions were taken regardless of temperature or weather. Some five years ago he could not disguise from himself that he was neither so robust as he had been nor so quick to recover from his periods of asthenia, and having no very close ties in London or in any part of the country he decided to try residence on the coast of North Devon, possibly being attracted to the neighbourhood by his late mother's connexion with it. At first the change did him good, if only because he made Devonshire his home and obtained the rest that he had never had when his time was divided between a Surrey house, a Suffolk cottage, and London chambers. But unfortunately in January of last year he contracted typhoid fever. Somewhat to the surprise of his medical attendants he pulled through a long and severe attack, in which on several occasions extreme prostration seemed to forbid hope. Then after a slow convalescence he seemed to have made a good recovery. A relapse, however, occurred in Florence last week in exceptionally pathetic circumstances. He was on his wedding journey, having married in April last, when an attack of hæmatemesis led to the end.

Sisley, as has been said, was not at all well known in the medical profession. He concealed his great kindness of heart by his sarcastic manner, he made little use of his erudition save anonymously in our columns or among his intimate friends in conversation at the Savile Club, he never spoke at learned societies, and he wrote no purely medical papers save the monograph on influenza to which we have referred. But those who did know him know that it was an unfortunate chapter of accidents which deterred him from securing the position in his profession which his originality of conception and sincerity of design must have won for him. And they will also feel that they have lost in him a remarkably loyal friend. He was a man of very few intimacies, but to be his friend was absolutely to command him, his time, his house, his purse, and his best thoughts. His young widow may feel assured that she has the deepest sympathy of all her husband's friends in her tragic loss.

GEORGE RICHARD SAUNDERS, M.B., B.C. CANTAB., L.R.C.P. LOND., M.R.C.S. ENG.

WE regret to announce the death on Feb. 25th of Dr. G. R. Saunders of Wanganui, New Zealand, at the comparatively early age of 50 years. Dr. Saunders was the eldest son of Deputy Inspector-General George Saunders, M.D., C.B., and was born at Buttevant, co. Cork, on July 25th, 1853. He was educated privately and subsequently went up to Caius College, Cambridge, in 1871. At about this time, we believe, he also entered his name as a medical student at St. Bartholomew's Hospital, London, mainly, if tradition can be relied upon (and we fancy the story is true), with the view of being able to compete in one of the sprint races in the inter-hospital sports on behalf of that hospital which by his aid is said to have won the odd event and thereby the Shield that year. During this period he probably devoted himself more to the athletic and social sides of university life than to hard reading and some time later he went out to New Zealand where he was for a while engaged in teaching and other scholastic work; he held the appointment of head-master of the Wanganui Collegiate School for some years and this school owes much of its present success to his efforts. While in New Zealand he met the lady who became his wife and his very happy marriage, together with the earnest wish of his friends at home, seems to have impressed him with the necessity of returning to England and completing his medical education. This, much to his credit, he successfully accomplished. Going back to St. Bartholomew's Hospital and passing his time between there and Cambridge he worked hard and in 1883 took his B.A. degree and subsequently in 1889 the M.B. and B.C. degrees of that university. In 1890 he also became L.R.C.P. Lond. and M.R.C.S. Eng. Having completed his medical education he returned to New Zealand and settled down in Wanganui where he became a well-known practitioner. He was on the staff of the Wanganui Hospital for some years and was consulting surgeon to that institution at the time of his death. He published a useful little work on infant feeding and children's diseases and was regarded in New Zealand as an authority in this particular branch of his work. In 1901 he had the honour of being chosen president of the New Zealand branch of the British Medical Association and he delivered an excellent opening address which was published at length in our columns on Jan. 11th, 1902, p. 69. Although many (alas, perhaps the majority) of those whom he delighted to call his friends at Cambridge have passed away there are still Cambridge men of the early "seventies" and many old St. Bartholomew's men who will feel a sense of deep personal loss when they hear of the death of George Saunders. He was eminently a good and sincere friend and his cheery, hearty, breezy manner endeared him to those who knew him well. An old friend and fellow student describes him as one of the most generous and open-handed of "pals" and recalls many instances both of his kindness and of his keen sense of humour. During his last illness, which was of a very painful nature, those about him spoke of his gentleness, his patience, and his fear of giving trouble. All these qualities were eminently characteristic of the man. Shortly after his return to New Zealand in 1890 he had the misfortune to meet with a very serious accident by being thrown from his horse and this necessitated his return to England for a period of some nine months.

He was devoted to all manly sports and took the keenest interest in athletics, nothing delighting him more than a sporting match with himself as one of the principals. One of the happiest days of his life witnessed his elder son's success (when a boy of six) in an open handicap sprint race at the old Lillie Bridge grounds.

Dr. Saunders had done welcome service for THE LANCET, having for a good many years occupied the position of our special correspondent in New Zealand. To the widow and two sons who are left to lament the loss of one of the very best of husbands and fathers we tender our sincere sympathy.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Tommasoli, professor of dermatology in Palermo.—Dr. A. B. Arnold, formerly professor of neurology in the Baltimore College of Physicians and Surgeons.—Dr. Bruchon, professor of anatomy in Besançon.—Dr. F. Holcombe, formerly professor of ophthalmology in New York University Medical College.—Dr. Ch. Rouget, formerly professor of physiology in Montpellier.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the third examination for medical and surgical degrees, Easter term, the following candidates were successful:—

Part II. Surgery, Midwifery, and Medicine.—A. E. Barclay, M.A., Christ's; H. J. D. Birkett, B.A., Trinity; E. M. Brown, B.A., and S. Child, B.A., Pembroke; R. A. Clapham, B.A., Emmanuel; G. H. Colt, B.A., Sidney Sussex; A. W. D. Coventon, B.A., W. L. Cripps, B.A., H. M. Davies, B.A., and R. G. Elwell, B.A., Trinity; H. Falk, B.A., King's; G. R. Footner, B.A., Pembroke; D. H. Fraser, B.A., Caius; J. Goss, B.A., Jesus; C. F. Hadfield, M.A., and Everard Harrison, B.A., Trinity; W. Hastings, B.A., Christ's; T. G. M. Hine, M.A., and H. F. Horne, B.A., King's; W. E. Hume, B.A., Pembroke; K. H. A. Kellie, B.A., Caius; J. Lambert, B.A., Downing; R. O. Lee, B.A., Emmanuel; T. C. Lucas, B.A., Clare; S. M. Mackenzie, B.A., Trinity; C. W. F. Moffatt, B.A., Clare; W. M. Mollison, B.A., King's; A. R. Moore, B.A., Caius; R. F. Moore, B.A., Christ's; W. V. Naish, M.A., Emmanuel; R. G. Nothwanger, M.A., and C. T. MacL. Plowright, B.A., St. John's; C. A. W. Pope, B.A., H. Rischbeith, M.A., and R. H. Robbins, B.A., Trinity; B. H. Stewart, B.A., Jesus; C. Stiebel, Trinity Hall; G. A. Ticehurst, B.A., St. John's; H. N. Whitting, B.A., King's; and B. A. Worthington, B.A., Clare.

UNIVERSITY OF OXFORD.—In a Congregation held on April 28th the following degrees were conferred:—

Doctor of Medicine.—Thomas Edwyn Cecil Cole, Christ Church.
Bachelor of Medicine and Surgery.—William Edward Blackall, Non-Collegiate.

TRINITY COLLEGE, DUBLIN.—At the previous medical examination the following passed in the subjects indicated:

[illegible] in Du P.

[illegible] y, David

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Hugo Liepmann, *privat-docent* of Neurology and Psychiatry, has been granted the title of Professor.—*Buenos Ayres:* Dr. Diogenes Decond and Dr. Juan B. Justo have been appointed Professors of Clinical Surgery.—*Constantinople:* Dr. Rieder is retiring from the Directorship of the Medical School at Gülhane on account of the failure of his health. His assistant, Dr. Deycke, has been appointed to succeed him.—*Erlangen:* Dr. F. Jamin has been recognised as *privat docent* of Internal Medicine.—*Florence:* Dr. Teodoro Stori has been recognised as *privat docent* of Operative Medicine.—*Gratz:* Dr. Oskar Zoth of Innsbruck has been appointed Professor of Physiology.—Dr. Friedrich Pregl has been appointed Extraordinary Professor of Physiological Chemistry.—*Greifswald:* Dr. Sötbeer of Heidelberg has been recognised as *privat-docent* of Internal Medicine.—*Kieff:* Dr. Ianichevski has been recognised as *privat-docent* of Neurology.—*Naples:* Dr. Guglielmo Mondio has been recognised as *privat-docent* of Psychiatry and Neurology and Dr. Raffaele Albenzio as *privat-docent* of Midwifery and Gynæcology.—*Odessa:* Dr. A. Fawicki of St. Petersburg has been appointed to the chair of Clinical Therapeutics.—*Pavia:* Dr. Pier Francesco Arullani has been recognised as *privat-docent* of Neurology.—*Stockholm:* Dr. Henry Isaac Marcus has been recognised as *privat-docent* of Psychiatry.—*Strasburg:* Dr. Asch has been recognised as *privat-docent* of Urinary Diseases and Dr. E. Schlesinger as *privat-docent* of Children's Diseases.

ROYAL COLLEGE OF SURGEONS IN IRELAND: GENERAL MEETING AND ELECTION OF OFFICERS.—A meeting of the Fellows will be held on Saturday, June 4th, at 1 o'clock, to receive the annual report of the Council. A meeting will also be held on Monday, June 6th, at 1 o'clock, pursuant to the provisions of the Charters, to elect a president, vice-president, council, and secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office should signify their wish by letter to the registrar, at the College, on or before Tuesday, May 24th, as it is necessary to include the names in the voting papers which are forwarded to the Fellows, and no candidate is eligible unless his application is received within the date specified.

MANCHESTER SOUTHERN HOSPITAL.—The report of the committee of the Manchester Southern Hospital tells of important work done on insufficient means. The number of patients treated during the year was 5805 and at the Maternity Hospital 1820 cases were attended to. The expenditure was £4311 and the income £2962, leaving a deficit of £1349. It may be remembered that it was intended to remove the hospital to Stanley Grove and that a site which had been acquired there was wanted for the new Royal Infirmary. An amicable arrangement was made, the infirmary giving about £15,000 to the Southern Hospital which has a site in close proximity to that which was given up. It is expected that possession of the new site will be obtained during the summer. It is intended to begin the erection of the first portion of a new hospital for about 60 beds on a portion of the site, and when possession of the remainder is acquired rooms for 40 additional beds and the administration block, &c., will be built. The Lord Mayor, in moving the adoption of the report, said that the hospital conferred benefits over a very large area in South Lancashire, and that it ought to be supported more generously. Dr. A. Hopkinson spoke of the advantages of the cooperation [illegible] uthern Hospital and the [illegible] the hospital a future of [illegible] pain and distress, but in [illegible] tes for the medical pro- [illegible] of the infirmary board; pointed with satisfaction to the fact that the negotiations between the hospital and the infirmary had been conducted without the slightest difficulty.

MEDICAL GOLF TOURNAMENT.—We are asked to remind our readers that the seventh annual medical golf tournament will be held on Thursday, June 9th, on the course of the Northwood Golf Club. The events comprise 18 holes match play *v.* Bogey and a foursome sweepstake competition *v.* Bogey. Particulars may be obtained from Mr. Rolf Creasy, Windlesham, Surrey.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the presentation of certificates and medallions to the successful candidates of the St. Austell (Cornwall) branch of the St. John Ambulance Association, on May 3rd, Mr. Archibald Shaw, M.D., C.M. Glasg., was presented with an oak stationery cabinet as a mark of appreciation for his services as honorary instructor.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—His Grace the Duke of Argyll, P.C., K.T., G.C.M.G., G.C.V.O., &c., will preside at the festival dinner of this hospital to be held on Monday, June 20th next, at 8 P.M. (Monday after Ascot), in the new rooms at the Savoy Hotel. It is hoped that any ladies or gentlemen willing to attend the dinner as stewards or to act as hosts and hostesses, bringing their own parties, will kindly send in their names as early as possible. There will be no payment for dinner tickets and separate tables to accommodate any number of friends (from two to 50) can now be reserved without charge. The ladies' committee, over which H.R.H. the Duchess of Albany presides, is giving its coöperation and support. The details are in the hands of the Social Bureau, 30, New Bond street, but information can be obtained from the ladies' committee, the managing director of the Savoy Hotel, or at the hospital.

WHITSUNTIDE ON THE CONTINENT.—Cheap tickets available for eight days will be issued by the Great Eastern Railway Company to Brussels, May 18th to 21st inclusive and May 23rd, *viâ* Harwich and Antwerp. Passengers leaving London in the evening reach Brussels next morning after passing the night on board the steamer. For visiting the Hague, Amsterdam, Utrecht, and other parts of Holland, the Rhine, North and South Germany, and Bâle for Switzerland special facilities are offered *viâ* the Great Eastern Railway Company's Royal British Mail Harwich-Hook of Holland route; through carriages and restaurant cars run in the North and South German express trains to Cologne, Bâle, and Berlin, reaching Cologne at noon and Bâle and Berlin in the evening. The General Steam Navigation Company's fast passenger steamers will leave Harwich on May 18th and 21st for Hamburg, returning on May 22nd and May 25th. The United Steamship Company of Copenhagen Royal Mail steamers will leave Harwich for Esbjerg, on the west coast of Denmark, on Thursday, May 19th, and Saturday, May 21st, returning on Tuesday, May 24th, and Wednesday, May 25th.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on May 9th, the Duke of Northumberland, K.G., the President, being in the chair. The President announced that he had nominated the following vice-presidents for the ensuing year: Sir William Abney, K.C.B., Mr. Shelford Bidwell, Right Hon. Lord Kelvin, Dr. Ludwig Mond, Sir Thomas H. Sanderson, G.C.B., Sir Felix Semon, Sir James Crichton-Browne (treasurer), and Sir William Crookes (honorary secretary). The following were elected honorary members: Professor E. H. Amagat, [illegible] J. N. Craft, Professor H. [illegible] Professor E. C. Pickering, [illegible] fessor H. L. Le Chatelier, Professor G. Lippmann, Professor J. W. Bruhl, Professor G. H. Quincke, Professor E. Fischer, Professor F. W. G. Kohlrausch, Professor H. Landolt, Professor L. Boltzmann, Dr. H. Kamerlingh Onnes, Dr. G. Lunge, Professor P. T. Cleve, and Professor P. Zeemann. The special thanks of the members were returned to Mrs. Frank Lawson and to Sir Thomas Sanderson for their donations to the Fund for the Promotion of Experimental Research at Low Temperatures. The following were elected members: Mr. P. M. Brophy, Mr. W. J. Canter, Mr. Eyre Crowe, Mr. H. T. Ellis, Miss E. Morgan, Mr. Berkeley Portman, and Mr. Burnett Tabrum, J.P.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bain, J. Gordon, M.B., C.M. Glasg., has been re-appointed a Member of the Medical Staff of the Wellington and District Cottage Hospital.

Barclay, William John, M.D., F.R.C.S. Edin., has been appointed Port Health Officer for the Port of Oamaru, New Zealand.

Bevan, Arthur, M.D. Lond., M.R.C.S. Eng , L R.C.P. Lond., has been appointed Anæsthetist to St. Thomas's Hospital.

Brown, A. T. F., M.B. Durh., has been appointed Certifying Surgeon under the Factory Act for the Chatham District of the County of Kent.

Dingle, C. V., M.D. Durh., has been appointed Medical Officer to the Tees Port Sanitary Authority.

Fletcher, H. Morley, M.D., F.R.C.P. Lond., has been appointed Assistant Physician to St. Bartholomew's Hospital.

Hillyar, C. B., L.R C.P., L.R.C.S. Edin., has been re-appointed a Member of the Medical Staff of the Wellington and District Cottage Hospital.

Horner, W. E L , M.D , B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health to the United Urban District of Wolstanton, Stoke-on-Trent.

Kennedy, A. J., L.S.A., has been appointed Certifying Surgeon under the Factory Act for the Shepley District of the County of York.

Lee, W. H., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the new Isolation Hospital at Morton, Yorkshire.

MacGregor, D. A., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Denby Dale District of the County of York.

Martin, John Middleton, M.B., B.Ch., D.P.H. Cantab., has been re appointed Medical Officer of Health for the Stroud (Gloucestershire) Urban District.

Meredith, John, M D., L.R.C.S. Edin., has been re appointed a Member of the Medical Staff of the Wellington and District Cottage Hospital.

Meredith, R. W. H., L R.C.P. Lond., M.R.C.S., has been re-appointed a Member of the Medical Staff of the Wellington and District Cottage Hospital.

Philipson, Sir George Hare, M.D. Cantab., M.D. Durh , D.C.L., LL.D., has been elected President of the Newcastle Royal Infirmary.

Reid, J., M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory Act for the Portsoy District of the County of Banff.

Robertshaw, W. M., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Stocksbridge District of the County of York.

Shaw, W. F., M.B., Ch.B. Vict., has been appointed Resident Medical Officer to St. Mary's Hospital for Women and Children, Manchester.

Smith, Enid Marian, M B., B S. Lond., has been appointed Senior House Surgeon at the Victoria Hospital, Hull.

Tivy, Cecil B. F., M B., B.Ch., B.A.O. R.U.I., has been appointed Assistant House Surgeon to the Staffordshire General Infirmary, Stafford.

Wilson, R. Appleton, M.D., C M. Edin., has been re-appointed a Member of the Medical Staff of the Wellington and District Cottage Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service, War Office.—Examination for not less than 30 Commissions in the Royal Army Medical Corps.

Bournemouth, Royal Victoria Hospital.—Honorary Medical Officer for Electrical Department.

Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

Bury St. Edmunds, West Suffolk General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Dublin, Richmond District Asylum.—Clinical Assistant for six months. Salary at rate of £60 per annum, with apartments and rations.

Dumfries and Galloway Royal Infirmary.—House Surgeon. Salary £50 per annum, with board and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E —House Physician for six months. Honorarium of £25, with board, residence, &c

Ebbw Vale Workmen's Medical Fund.—Assistant Medical Officer at Beaufort and Assistant Medical Officer at Victoria. Salary in each case £200 per annum.

Evelina Hospital for Sick Children, Southwark.—House Surgeon. Salary £80, with board, residence, and washing. Also Surgeon to Out-patients

Finchley Urban District.—Medical Officer of Health. Salary £200 per annum and fees.

Glasgow Parish Council Barnhill Poorhouse, Springburn.—Resident Medical Officer. Salary £250 per annum, rising to £350, with board and lodging.

Hastings, St. Leonards, and East Sussex Hospital, Hastings.—Physician.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, washing allowance £2 10s., with board and residence.

Indian Medical Service, India Office.—13 Commissions in Indian Medical Service.

Lanark County Council.—Assistant Medical Officer of Health. Salary £140 per annum, with travelling expenses.

Leeds, General Infirmary.—House Physician. Board, lodging, and washing provided.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100, with board and lodgings.

London Hospital, Whitechapel, E.—Surgical Registrar.

London Lock Hospital, 91, Dean-street, W.—Surgeon to Out-patients.

London (Royal Free Hospital) School of Medicine for Women, 8, Hunter-street, Brunswick-square, W.C.—Lecturer on Anatomy.

London Throat Hospital, 204, Great Portland-street, W.—Third Honorar [illegible]

Manitoba, [illegible] Professorships in Botany (including Geology [illegible] Mineralogy and Crystallography), Chemist[illegible], [illegible], [illegible]siology (including Zoology). Salary $2500.

Miller Hospital and Royal Kent Dispensary, Greenwich road, S.E.—Junior Resident Medical Officer for six months. Salary £80 per annum, with board, attendance, and washing.

New Hospital for Women, [illegible] Physician, House Surgeon, and Residen[illegible]

Norfolk and Norwich Hospital. [illegible]

North-West London Hospital, Kentish Town road.—Resident Medical Officer and Assistant Resident Medical Officer, each for six months. Salaries at rate of £50 per annum, with board, residence, and washing. Also Second Honorary Anæsthetist.

Plymouth, South Devon and East Cornwall Hospital.—House Surgeon. Salary £100, with board, residence, and washing.

Reeth Union, North Yorks.—Medical Officer of Health and District Medical Officer. Salary £95 per annum and fees.

Royal College of Surgeons of England.—Hunterian Professors, the Erasmus Wilson Lecturer, and the Arris and Gale Lecturer.

Royal London Ophthalmic Hospital, City road, E.C.—Third House Surgeon. Salary £50, with board and residence.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Clinical Assistants for six months.

St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.—Honorary Assistant Anæsthetist. Also Honorary Dentist.

St. Peter's Hospital for Stone, etc., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing. Also six Clinical Assistants for six months.

Scarboro' Hospital and Dispensary.—Junior House Surgeon for six months. Salary £80, with board and residence.

Sheffield Children's Hospital.—Lady House Surgeon. Salary £80 per annum, with board, lodging, and washing.

Sheffield Royal Infirmary.—Junior Assistant House Surgeon. Salary £70 per annum, with board, lodging, and washing.

Sussex County Hospital.—Second House Surgeon, unmarried. Salary £60 per annum, with board, residence, and washing.

Valkenberg Asylum, near Cape Town.—Assistant Medical Officer, unmarried. Salary £250 per annum, rising to £300, with board, lodging, and washing.

Victoria Hospital for Children, Tite-street, Chelsea, S W.—House Surgeon for six months. Honorarium of £25, with board and lodging.

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon, unmarried. Salary £100, with apartments, board, and service.

West London Hospital, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry provided.

Western General Dispensary, Marylebone-road.—Second House Surgeon, unmarried. Salary £80 per annum, with board, residence, and laundry.

Westminster General Dispensary.—Resident Medical Officer. Salary at rate of £120 per annum, with rooms, gas, coal, and attendance.

York County Hospital.—House Physician. Salary £100 per annum, with board, residence, and washing.

York Dispensary.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

Stiff.—On May 10th, at Bury St. Edmunds, the wife of Harold Stiff, M.B. Cantab., of a daughter.

Unitt.—On May 4th, at Quorn, Leicestershire, the wife of James Arthur Unitt, L R.C.P., M.R.C.S., of a son.

White.—On April 18th, at Vanbrugh-park, Blackheath, S.E., the wife of Finch White, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGE.

Smith—Ross.—On April 18th, at Harlech Villa, Dunoon, by the Rev. R. S. Macmorran, M.A., and the Rev. J. W. Girvan, William Smith, M.B. Lond., of Brabourne, Kent, to Mary Tulloch, youngest daughter of B. C. Ross, Esq., of 4, Ardgowan-square, Greenock.

DEATHS.

Horden.—On May 5th, at Brixton-hill, S.W., suddenly, Herbert Henry Horden, M.D. Lond., M.R.C.S., L.R.C.P.

Sisley.—On May 7th, at Florence, Richard Sisley, M.D., of Saunton, Braunton, N. Devon, aged 47.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN INTERESTING POINT IN A GENERAL PRACTITIONER'S ACCOUNT.

A CASE of some interest came before his honour Judge Stonor and a jury on May 4th at Brompton. The plaintiff was a medical man practising in Chelsea and he sought to recover £23 from a retired army officer. The claim was in respect of professional attendance upon various members of the defendant's family, but principally upon a son, about eight years of age. The account originally amounted to a little over £50; cheques had, however, been paid from time to time. It was thought at first that the little lad suffered from stone in the bladder but an operation revealed the presence of a piece of wood in that organ. A communication was discovered from the bowel into the bladder. The wood had the *resemblance of an apple stalk and it appeared to have ulcerated* the bowel and then to have worked into the bladder. A first operation was performed by the present plaintiff, but a subsequent one was carried out by another surgeon, and an important point in dispute was whether the plaintiff was entitled to charge for assisting at this operation. The defendant said that he did not engage the plaintiff to assist. The plaintiff, on the other hand, said that it would have been a most exceptional procedure had he, as the boy's regular medical attendant, not been [illegible] charging an inclusive [illegible] from also charging for [illegible] produce his books, when the defendant's counsel discovered that 12 guineas had first been put [illegible] and 15 guineas afterwards [illegible] impressions" were generally [illegible] fairness to himself he was [illegible]ely the jury found in favour of the plaintiff for the full amount claimed and his honour gave judgment accordingly.

In our opinion no other decision was possible.

THE QUESTION OF ADMISSION TO HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I should be glad if you could let me have some idea of the procedure to be followed to obtain the admission of a patient into one of the London general hospitals.

To-day I was called to a patient who had broken her patella. I improvised a back splint, bandaged, and sent her to the hospital. Her [illegible] me and state that after a long delay [illegible] attention) she was refused admission [illegible] As I sent her in hoping that she would have been operated on I am naturally surprised at the action of the authorities of the hospital. If there is any book, pamphlet, &c., which gives any information as to routine to be observed I should be glad to know. I am, Sirs, yours faithfully,

May 10th, 1904. W. A. T.

*** The decision as to whether a patient should or should not be admitted to a hospital rests with the officer of the hospital in charge of the admission room. Some hospitals require letters and some do not. We can hardly imagine that if the case mentioned had been one for operation—i.e., if the surgeons considered operation necessary and the patient had consented—admission would have been refused if there was a bed available.—ED. L.

PRECAUTION AGAINST BUGS.

A CORRESPONDENT writes to ask us if we can inform him of some method of protection against the attacks of bugs. If the bugs simply live in the walls of the room the simplest plan is to move the bedstead away from the wall and to place its feet in tins of water or oil. If, however, the bugs inhabit the bedstead, and we gather from our correspondent's letter that this is probably the case, the only certain method of preventing their attacks is the use of the following apparatus, called, from its inventor, the "Levinge." The "Levinge" consists of an ⅃ shaped sack, one arm of which is made of calico or fine linen and the other arm of muslin. In the linen (horizontal) part the sleeper lies, the end where the feet come being closed. The end of the muslin (vertical) part is open with a tape run round the opening, and about a foot or 18 inches from the opening is a hoop. The sleeper gets into the sack through the opening, tightens up the said opening and fastens it firmly by means of the tape running in the hem and suspends the tapes to a hoop or to a nail driven into the wall. It will thus be seen that he is inclosed in a chamber which is quite impermeable to a bug. The hoop serves to keep open the portion of the "Levinge" which covers his face. The only objection to this apparatus is that in very hot weather it is apt to be somewhat oppressive but such a complication is not likely to arise at the place to which our correspondent says that he is going. In our experience no so-called insect powders are of the slightest use against bugs.

A COMPLICATED LIABILITY.

A KINGSWOOD woman fractured her thigh recently, a medical man was sent for, and he advised her removal to the Bristol Royal Infirmary and as the patient was destitute communicated with the relieving officer. The woman was taken to the infirmary and the person who provided the cab sent a bill for 6*s.* to the relieving officer. This was brought before the Warmley guardians and there was an animated discussion at several meetings as to who was liable to pay. At first the guardians endeavoured to make the husband pay but he refused as he was living apart from her and said she was a member of the club of the medical man who was sent for to attend her. The guardians then applied to the medical man for the money. He replied that he did not order the cab, it was ordered by the relieving officer. Eventually the guardians sued the woman herself in the Bristol county court for the 6*s.* Her defence was that she never ordered the cab and it was against her wish that she was taken to the infirmary. She further stated that she did not remain in the institution and paid 5*s.* for a cab to take her home. [illegible] Ige [illegible] to [illegible] the Warmley guardians will now take in the little comedy.

THE CRUELTY OF FRIENDS.

THE paragraph which follows appeared in the *Midland Counties Tribune* of April 29th:—

> Mr. and Mrs. L——, ——, desire to thank many friends for kind inquiries, and to say that their son has successfully undergone the operation for appendicitis. Their sincere thanks are also tendered to Dr. J——, the operator, and Dr. P—— who administered the anæsthetic.

We have received a letter with regard to it from a medical practitioner who signs himself "Disgusted." We agree that the publicity is most unfortunate and that Mr. and Mrs. L. could hardly have done persons to whom they are grateful a worse service than advertising them in this manner. At the same time our correspondent will understand that no blame can attach to the medical men as they cannot be suspected of complicity.

MINOR SURGERY IN CLUB PRACTICE.

To the Editors of THE LANCET.

SIRS,—The question has been raised by a member of a club as to whether minor surgery is included in the fee for medical attendance. On taking the club no special agreement was made and I assumed that only purely medical attendance was to be given for the fee of 1*s.* per quarter. Is the committee right in contending that this is for minor surgery also? I should be obliged for advice, and desire to be guided by the usual custom in the matter.—I am, Sirs, yours faithfully,

C. E. S.

*** [illegible] advised to follow suit.—ED. L.

EYESTRAIN AND HEADACHE.

A CORRESPONDENT sends us the following joke from last week's number of our contemporary *Tit Bits* which he thinks has a direct bearing on the topical question of eyestrain and headache:—

> PATIENT: "I'm troubled with headaches in the morning. It may be on account of my eyes; perhaps I need stronger glasses."
>
> MEDICAL MAN: "No, I think you merely need weaker glasses—and fewer—at night."

GOATS AND RATS.

DR. George H. R. Dabbs in a letter to the *Westminster Gazette* of May 10th, referring to some recent remarks of Sir James Crichton-Browne on the goat as a milk source for the children of the poor, asks whether there is any truth in the prevalent idea in the Basque country that where goats are the rat is not. "Over and over again the Basque farmer has told me," he says, "that the rat will never come where the smell of the goat is. It is the only virtue, æsthetic or other, which I have ever known attributed to the rat, but if there is an antagonism of environment in the two animals Sir J. Crichton-Browne's recommendation may have an even wider value than he anticipates."

THE CHEMISTS' EXHIBITION.

AN exhibition full of interest to the drug and allied trades was opened at the National Skating Palace, Argyll-street, W., on May 9th. The occasion marked the tenth exhibition of the kind which has been held since the scheme was set on foot by the proprietors of the *British and Colonial Druggist.* The space in the skating palace was completely occupied with exhibits and the whole presented quite a picturesque effect. Most of the leading druggists were represented and the exhibits included pharmaceutical preparations, hygienic and sanitary products, photographic requisites, dietetic specialities, and a thousand and one other articles which are now recognised as inseparable from the pharmacist's business. A feature of the exhibition was an admirable series of photographs and a collection of photographic apparatus. Demonstrations were also given of the properties of radium, helium, krypton, and argon. At one stall was exhibited a splendid collection of crystals of chloride of gold which was stated to be worth close upon £2000. There was a very satisfactory attendance of members of the trade from all parts of the world and there were many members of the medical profession present who took an evident interest in the exhibits. The organisers may be congratutated on the continued success of this interesting annual event.

LONDON POST-GRADUATE ASSOCIATION.

THE scheme for providing clinical instruction for qualified medical men on a cooperative basis in the metropolitan hospitals continues to do good work. It is satisfactory to learn that a number of the ticket-holders renew their tickets after trying the scheme for a period of three months, thus showing their satisfaction with the plan. The scheme is already so well known that it is not necessary to recapitulate the advantages provided by a single ticket which secures admission to the 16 different hospitals forming the association for the very moderate fee of seven guineas for three months or ten guineas for six months. For those who desire to see as many cases as possible in a short period a wealth of material is thus made available and practitioners who desire to keep up to date in their clinical work will find here the most ample opportunities for doing so. Particulars may be obtained by writing to the Secretary, London Post-Graduate Association, Examination Hall, Victoria Embankment, London, W.C., or by interview between the hours *of 11 30 and 1 or of 2 and 3, except on Saturday.*

HOLMAN TESTIMONIAL FUND.

THE following further list of contributions has been forwarded to us by the honorary treasurer of this fund, Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., by whom or by the secretary, Mr. W. A. Berridge, Oakfield, Redhill, Surrey, subscriptions will be received:—

AN UNSUSPECTED SOURCE OF AN OBJECTIONABLE PARASITE.

IN reference to a paragraph under the heading of "Clean Heads" in the letter from our Manchester correspondent (vide THE LANCET, May 7th, p. 1311) we have received an interesting communication which suggests an unsuspected way in which pediculi may be conveyed to the human body. A child living in a suburb of London occasionally had her head washed in rain water obtained from the rain-water pipe which ran down the side of the house. This water was heated, though perhaps not to the boiling point, and then cooled with cold water from the tap. From time to time pediculi were found on the head of the child and as she did not often meet other children and the children she did meet were above suspicion the source of the objectionable parasite remained a profound mystery until it was noticed that the appearance of the pediculi synchronised with the washing of the child's head in rain water. On discontinuing the use of rain water the trouble ceased. Subsequently lice were found in water obtained from the rain-water pipe and our correspondent suggests that they must have been washed from the nests of sparrows which were known to be in the gutter supplying the pipe. This seems to be the only feasible explanation of a curious occurrence.

WATER SUPPLY.

To the Editors of THE LANCET.

SIRS,—A gravel pit is being opened about three-quarters of a mile from the village in which I live. The output is to be about 800 to 1000 tons of gravel a day for three years. The village lies between the pit and the river. The district is very flat and only about 40 feet above sea level. The water level is about seven feet from the surface. The bed of gravel is some 11 feet 6 inches deep and is to be worked out. At about ten feet deep constant pumping is required. The general character of the soil is sandy gravel. The water-supply of the village is entirely from wells. What is likely to be the effect on the water-supply (if any), and can any steps be taken in the matter?

I am, Sirs, yours faithfully,

May 10th, 1904. CIGARETTE.

AN ABNORMAL CLINICAL THERMOMETER.

WILL a correspondent who sent to us recently a clinical thermometer incorrectly graduated kindly supply us with his name and address?

◆

Schoolmaster.—We do not think that there could be any objection to the sick rooms of a school house being in connexion with the main body of the building by means of a covered way, seeing that the sick rooms have a separate entrance. We do not gather from our correspondent's letter whether the buildings are in process of erection or are already built, but supposing that it is decided to make the sick room building entirely separate from the other there is no danger or difficulty in moving a patient, even though the weather be bad, provided that he be well wrapped up. The risk of infection lies not so much in aerial conveyance from one building to the other as in the chances of infection being conveyed by attendants or by the common use of spoons, forks, crockery, and the like, by the patient and the other boys without thorough cleansing and disinfection of the same.

M.D. Lond.—Among the latest books dealing with hypnotism is "Hypnotism: its History, Practice, and Theory," by J. Milne Bramwell, M.B., C.M. Edin. Price 18*s.* net. Published by Grant Richards, 48, Leicester-square, W.C. The following books by Dr. Alfred T. Schofield and published by Messrs. J. and A. Churchill, 7, Great Marlborough-street, W., also contain references to the subject: "The Force of Mind; or, the Mental Factor in Medicine." Price 5*s.* net. "The Unconscious Mind." Price 7*s.* 6*d.* "Unconscious Therapeutics; or, the Personality of the Physician." Price 5*s.* net.

Strathcona.—There is nothing illegal in having the notices printed but we do not quite understand to whom they are to be sent. If they are to be distributed broadcast to the public—i.e., to the patients of other medical men—the procedure will be quite wrong. There is no difference between such a method of establishing a *clientèle* and canvassing or open advertisement.

R.—(1) Our correspondent must supply us with a copy of the rules and regulations of the society in question before we can answer his question. (2) No.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

Annual Oration

ON

THE FUTURE OF LONDON MEDICAL EDUCATION.

Delivered before the Medical Society of London on May 16th, 1904.

By SIR ISAMBARD OWEN, M.D CANTAB., F.R.C.P. LOND.,

VICE-DEAN OF THE FACULTY OF MEDICINE OF THE UNIVERSITY OF LONDON.

MR. PRESIDENT AND GENTLEMEN,—Some years ago I met a distinguished foreigner on his first visit to London. He said: "What a strange people you are in England. Your country has given birth to some of the greatest leaders of modern thought. Had we been fortunate enough to call them compatriots their monuments would have been conspicuous in our towns, the public places of our capital would have borne their honoured names. I have traversed London," he pursued, "without once being reminded that I was in the country of Darwin and of Spencer; the name even of Newton met my eye only at the corner of a back street off Holborn." I did my best to explain the apparent paradox. I traced in detail the principles of English street nomenclature; I urged the probability that the Newton of High Holborn was not the author of the "Principia" but a local builder; I pointed out that a London statue was the very last form of memorial a philosopher would wish for; but my companion went away only half satisfied and left me, to speak frankly, as unconvinced as himself. One cannot in candour deny that the contrast is somewhat odd between the commanding position in the history of science which England owes to the labours of a few of her gifted sons and the attitude of comparative indifference which the mass of contemporary Englishmen display, I will not say merely to the personal fame of their illustrious pioneers, but in general to the entire question of the advance of scientific knowledge within their bounds and to the development of the means of national education which that advance demands. Elsewhere in civilised Europe we are made conscious of a franker public recognition of the change that the last century made in the conditions of the modern world, of the extent to which the cultivation of exact knowledge has revolutionised the requirements of public and private business, and of the obligations and necessities which the new order of things has imposed on the community. Elsewhere than among ourselves it is not thought a strange thing that the resources of a State should be employed to extend the bounds of abstract knowledge; elsewhere we see the organisation of education no less an object of government than the ordering of the police or the control of the highway. Even in comparatively poor countries we [illegible] not say that the time has come when England should make up its mind whether the continental view of the requirements of the age is right or wrong? If it be right one cannot without concern view the extent to which this country has lagged behind. At present England speaks with uncertain voice and mind. She evinces no real conviction of the practical value of scientific knowledge or scientific training. Science is lauded to the skies in words and left to starve in fact. Research is commonly treated as though it were a matter of merely private ambition or concern. Commerce and industry are still in doubt whether any more scientific training is necessary for their employés than sufficed a century ago. In questions of public education, except as far as they may concern a point of religion, the generality of Englishmen hardly affect an interest.

The prevailing note of indifference belongs to no particular class or section. The country squire who regards schools as an insidious means of undermining agriculture may be matched by the industrial magnate who frankly despises all technical knowledge gained outside the workshop. The Minister who with difficulty consents to make a public grant for research has himself to wrap its object in some specious guise of "utility" lest the popular voice should condemn it as a dole to a privileged class. In the matter of public education half-heartedness has led us into a course as wasteful as it is illogical. For 30 years past, at a vast [illegible] educating the entire population [illegible] providing no means for those [illegible] of it to proceed further. If a national system of education is to produce a national advantage worth the money it costs its aim must surely be largely a selective one. The ultimate object, from a statesman's point of view, of national education is to bring the best brains of the country, or, to speak more precisely, the best combinations of brains and energy, to the front; to bring them into the positions in which they can be turned to the best account in the national struggle for supremacy. In England we have stopped at the first stage, the most costly and least remunerative. We have produced year by year a mass of educable material and made nothing further out of it. Whatever individual talent the elementary school may have revealed we have taken no care to insure its after-development. We have laid a costly foundation and built nothing upon it. Can we wonder that so many Englishmen regard national education as a failure and speak of it as a device to convert useful workmen into unnecessary clerks? If it be not so in fact it is not the fault of the policy that has been followed.

To all this there is a significant exception. John Bull's carelessness about science and education stops with the shore. When he has to deal with his own chosen element—the sea—he is altogether another man. In nautical matters no one values exact knowledge more; no one, unless perhaps his recent pupil in the Far East, has more assiduously cultivated scientific methods or been more careful of the training of the men to whom he entrusts his destinies. We need not, therefore, commit the absurdity of supposing indifference to science to be any permanent feature of the English character. It is but a passing phase, the origin of which we may discern in patent historical causes. Great Britain entered on the Victorian era under peculiar advantages. Our previous rivals in Europe had been exhausted by long wars which had brought us no greater disaster than increased taxation. America was still almost a negligible quantity. Our early use of coal and the mechanical inventions to which it had given rise had aided in giving us a long start of our contemporaries in the modern world which those inventions were bringing into being. Other nations might claim superiority in the graces of life; in commerce, in industry, in material civilisation generally, the United Kingdom for many years was easily ahead of them all. We fancied, perhaps, that this was to last for ever. Other nations had painfully set about the task of organising their resources, systematising their knowledge, trying to make the most of the human material they possessed; we had, we thought, no need to do the same; our natural energies and superior aptitude would always keep for us the supremacy we had gained. In matters of education England no less enjoyed during this period a pre eminence it has been difficult for her to forget. The universities of the continent had long been in a state of decay, material as well as intellectual. The last relics of the great mother University of Paris, that had once ranked in authority with Pope and Emperor, had disappeared in the Revolution; of her half hundred of colleges nearly all had vanished. The collegiate foundations of Oxford and Cambridge, on the contrary, had steadily grown in opulence and lost nothing of external splendour. In the middle of the last century Oxford and Cambridge, to say nothing of Eton and Winchester, were as far in advance of anything of the kind elsewhere as the commerce of the Thames or the industries of Lancashire. As was natural, Englishmen grew to regard their two ancient seats of learning as the type-universities of the world and the particular kind of education prevalent there as the ideal of what university education should be. Universities elsewhere have since multiplied and gathered resources; economic causes have diminished the income of our once wealthy colleges; but England is slow to realise the new situation. The appeals for help which Cambridge has been lately making to its wealthy alumni are passing almost unregarded and the great majority of Englishmen would still, I believe, be surprised to be told that, measured by contemporary European, to say nothing of American, standards, neither Oxford nor Cambridge would be reckoned among first-class universities.

Whether it be that we forgot, in the later years of the nineteenth century, a familiar apologue, whether it be that we had grown into the habit of relying too much on our natural advantages and neglecting the means of improving them, or thought that the world would stand still for us, certain it is that of late we seem to have awoke rather suddenly to the disagreeable fact that in some of the departments of the world's business in which we thought our supremacy most secure we are being overtaken, and possibly distanced, by countries that we scarcely regarded as rivals a generation ago. It is not only that the tortoise shows signs of overtaking the hare; the new world, we begin to find, has bred a hare at once fleeter and more persistent than ourselves. Now perhaps one may hope that a hearing will be given to those who have long been speaking to unwilling ears and calling attention to the neglected state of national education in the heart of the empire. We have long had it pointed out to us with what heed these matters were regarded in continental countries, how carefully their educational systems were thought out, how liberally even poor nations were voting money for educational purposes, but to all this little attention has been given, these things being apparently regarded as necessary only for the foreigner. Will Englishmen be equally careless of what is being done in the United States and in our own North American colonies? Americans can hardly be set down as a second-rate people, or an unpractical race, or an unsuccessful one. It may be that London will not disdain to learn something from them. There was published in London a few weeks back the report of the Mosely Educational Commission to the United States, the second of the two commissions which Mr. Alfred Mosely despatched at his own expense to endeavour to trace the cause of the success of Americans in their competition with ourselves. The commission included 26 men prominent in the British educational world; the reports they sent in run to 400 closely printed pages and every page is interesting reading. The contents may well startle this country, if anything can, out of its apathy with regard to the matter.

Everything, let me say at once, is not represented as perfect in American education. The commissioners found much to criticise in American educational methods, in their lack of thoroughness in certain directions, in a general tendency to underpay the *personnel* and in a certain disposition on the part of private benefactors to regard buildings and sites as of more importance than men. But these, it is frankly admitted, are faults of immaturity and over rapid growth; the greater part of the American educational institutions are barely a generation old. Nor did the commissioners find that thoughtful Americans were in the habit of looking on education as the source of their prosperity. That they were disposed rather to attribute to the inherent qualities of their composite and selected race. But, what was more significant, they regarded the national interest in education as the natural expression of the very qualities that made them successful and were confident that if their public education had not been the cause of their prosperity it was an essential condition of their prosperity being maintained.

American interest in education is not of recent origin. The practice of appropriation of public land to educational purposes by Act of the Federal Government dates from the early years of American independence and the most extensive measure of this kind was passed in the crisis of the Civil War. Up to the year 1900, as may be learned from the educational reports prepared for the Paris Exhibition, the United States Government had in this way assigned upwards of 86 000 000 acres, an area larger than the whole of the United Kingdom, out of the public domain for the support of education. The total value of Federal education grants in land and money to the same year, the land being valued only at its original selling figure, is stated by the same authorities to be nearly £60,000,000 This, it will be understood, is the grant of the Federal Government alone and has nothing to do with the contributions and levies of the separate States and their cities. Private benefaction has been on a still more remarkable scale. Private gifts and bequests for university education alone, says one of the Mosely commissioners, have amounted to £40,000,000 in the course of 30 years. £14 000,000 is given by one of the 1900 reports as the sum of the private benefactions of the single year preceding to universities, colleges, schools, and libraries. Mr. J. D. Rockefeller and others are said to have spent £4,000,000 on the University of Chicago and other recent foundations are reported to be still more royally endowed. Harvard, at the present time, draws an annual income of nearly or quite £200,000 from private benefactions. Though medicine is as yet the least favoured and one of the most backward branches of American education the special gifts to it are still far from contemptible. The medical department of the Columbia University of New York, for example, is endowed, including land and buildings, to the extent of £496,000, the site and buildings of the Jefferson Medical College of Philadelphia are valued at £120,000, and a recent benefaction to the medical department of Cornell University in the State of New York is rumoured to amount to £300,000. An imperfect return shows an aggregate of £3,000,000 of property enjoyed by medical education throughout the United States and during the five years 1894–98 private gifts to medical schools are reported as exceeding half a million sterling, being about a sixth of the benefactions made to hospitals during the same period. Of the universal American interest in public education, of the profound belief in the value of public education that possesses all classes in the United States, every chapter of the Mosely Reports is eloquent. Public bodies, we are repeatedly told, grudge no money spent on education, the claim of educational institutions to the best sites, the best buildings, the best appliances that can be obtained is regarded as incontestable; moneyed men are everywhere prompt to recognise the needs of education, industrial concerns are eager to secure the most highly educated men for their employment. The development of public education in the United States is still going actively forward and by all appearance will do so for many years to come.

It is sad to compare with these glowing pictures of educational progress the history of the 20 years of wasted opportunity and effort we have lately known in London, the 20 years of wearisome agitation, of interminable inquiries, of reiterated deputations, of bland official replies, of municipal and public apathy, that we went through before we could get so much as the bare framework of a teaching university in this the richest city of the world. May we hope that in the twentieth century London will turn its eyes to see what these vigorous young communities in America are doing, and that we shall not have to wait 20 years more before our hard earned framework is clothed with living material. In this country at least no form of higher education can claim a stronger title to public support than medical education. Its purpose is the interest of all. Disease and accident are no respecters of time and place; the life of the wealthiest may at any moment rest upon the skill and knowledge of the humblest village practitioner; failure at any point of the sanitary guard which in times of danger preserves a nation from epidemic disease may let in an enemy that will cost the country more than it could ever spend upon its medical schools. The medical profession is not one that can be charged with making a selfish or illiberal use of its knowledge. In all things it has loyally consulted the public advantage first of all. It is a profession of whose voluntary generosity the public never scruples to make unsparing—I had almost written unblushing—use, a profession which meets the heavy demands made upon it with unfailing patience and public spirit. I shall hardly overstate the fact if I assert that a fifth of the entire population of London has at one time or another, in the hour of distress, learned to rely on the public or private charity of the medical practitioner. Medicine, which gives so much and so readily, may surely ask a little in return and expect in all honour that its claims will be ungrudgingly met.

If the claim that medicine is about to make on the inhabitants of London has gone unrecognised till now it is not altogether the public fault. Medicine has perhaps desired too much to be independent and self-sufficing; we have not taken the public sufficiently into our confidence as to the needs of our art, we have troubled too little to see that it was adequately informed. The average non-medical person, it is safe to say, knows at the present day far less of what goes to the making of the medical practitioner than he does of almost any other form of professional education. The developments of medical education during the last quarter of a century have not been trumpeted abroad, "written up" in the press, or made the subject of magazine articles Of the London hospitals the London public knows much; of the schools of medicine that have grown up alongside of them almost nothing It would probably surprise the great majority of Londoners to learn that the mere buildings of these schools would in the aggregate suffice for the needs of many a renowned university, that upwards of four hundred teachers are actively engaged in connexion with them, and that the curriculum pursued in them is at once the most arduous and the most highly systematised form of education that exists in the country. The foreigner would be no less astonished to hear that the entire system has been the result of private effort and that until lately it has been entirely self-supporting. The buildings appropriated to its use in University College and King's College are almost the only public assistance it has to acknowledge; private liberality has hardly gone beyond the foundation of prizes and exhibitions. With the exception of certain professorships at University College there is not at the present moment a single endowed chair in any medical school in the metropolis. Like many other institutions in England, the London School of Medicine was not founded; it grew spontaneously in response to a need. It grew up in close connexion with the 12 great general hospitals, but till lately it had cost them nothing. On the contrary, they were pecuniarily the gainers by it. I ventured some six years ago to estimate that the existence of the medical schools virtually added no less than £50,000 a year to the charitable resources of London and I was not accused of exaggeration.

The endowment of a single professional faculty to the extent of some £24,000 a year, exclusive of premises and library, would seem in London the dream of a rather distant future, but that is the extent to which, in the neighbouring capital of France, the Faculty of Medicine appears to be subsidised from public sources. The statistics of higher education issued by the Ministry of Public Instruction for the ten years 1889–1899 show that in the last year reported on (1897–98) the sums assigned to the purpose of the Faculty amounted to 1,466,212 francs, of which only 859.302 francs were recouped from students' fees, leaving 606,910 francs, say £24 276, provided from public sources, chiefly the coffers of the State. The expenses of the Paris Faculty do not, it may be added, include those of instruction in what we term the "preliminary sciences."

A complete endowment of the Faculty of Medicine is not at present in question in London. We see no reason to apprehend that the schools of the London hospitals will be less able in the future than in the past to provide from their own resources for the professional education of as many students as their ample hospitals can accommodate; but there is a strong and growing sense of the need of relieving them from the increasing pressure of a burden which at present they are under the obligation of supporting, but which is properly none of theirs to bear. The medical curriculum has long since everywhere divided itself into two nearly separate portions, the one mainly professional, while the other tends more and more to become purely academic. It is within my own recollection and that of many here that the student of other days, while still pursuing his ordinary anatomical and physiological studies, in some cases while working only at the introductory physical and biological sciences, was expected or encouraged to spend a part of his time in the wards and out-patient rooms of his hospital and to familiarise himself thus early with the aspects of disease. That is now virtually at an end. The increasing requirements of the earlier parts of the curriculum have rendered it impracticable. The contemporary pupil, though nominally attached to a hospital, pursues as a general rule the first two years, or three as the case may be, of his curriculum under almost purely academic conditions and rarely enters a medical or surgical clinique for any serious purpose until he has surmounted the barrier of his anatomical and physiological examinations.

I need not stop to discuss whether the change of practice is of unmixed advantage or no. Something, it will doubtless be said, is lost in the present day which the older and less differentiated plan of education was able to impart, but this, I fear, is a profitless question to raise. The present system is universal, or nearly so; it has forced, or is forcing, itself by the logic of circumstances on every seat of medical education alike and it must be taken as one of the facts of the case that we have to deal with. In almost every place of medical education except London a further differentiation has already taken place. The responsibility of providing for the earlier portion of the curriculum has ceased to rest upon the medical school properly so called. In Lancashire and Yorkshire, in Birmingham and Newcastle, and in Wales endowed universities and university colleges have taken this part of the work upon themselves, leaving the schools of medicine, in the strict sense of the term, to their proper task of teaching the theory and practice of medicine and surgery and such of the more advanced branches of science as cannot conveniently be separated from clinical work. In London, without a central teaching authority to assist, to lead, or to coördinate the scattered educational agencies at work in her vast area, this further step has till now been impossible. The medical schools, unendowed and without external aid as they are, have had to bear the burden of the preliminary education themselves. Each separate school, in order to maintain its position, has found itself obliged to offer a medical curriculum complete in all its parts, academic as well as professional, and to provide the buildings, laboratories, and external teachers necessary to make it so. Until London possessed a university in fact as well as in name no practical way out of the difficulty could be seen and the difficulty has been a steadily increasing one. While politicians disputed whether 5,000,000 of population should have two titular universities or only one, whether professors of European fame should be dealt with as honourable men or objects of public suspicion, and how far the laying of academic hands on the London matriculation examination would endanger that palladium of British learning, the men who were actually doing the work had to strain every nerve to meet the constantly growing requirements of the long medical curriculum and to keep the London schools of medicine on a level worthy of their historic fame. The work was done. It has, I venture to say, been well done; but the strain on the schools has been no light one and its tendency is still to increase. Over the schools hangs the shadow of the ominous question, How long can the present strain be maintained? A limit will be reached, it must be plainly said, unless London awakes to some sense of its responsibility in the matter. And while London is asleep the provinces are moving. I trust I shall not be understood as saying one word in dispraise of the excellent teaching given in many of the provincial medical schools or in derogation of the highly distinguished physicians and surgeons who are working so ably in them, but the fact nevertheless remains not only that London possesses an unexampled field of clinical instruction but that as long as the greatest prizes of the profession are to be found in the capital the tendency must be for the best clinical talent in the profession to be attracted to the metropolitan hospitals and schools. It would, I will not hesitate to [illegible] Londoners but to England anc [illegible] should ever lose the position i [illegible] seat of medical education in the country. It is to the grave discredit of so wealthy a capital that such an event should be even imaginable.

Thanks to the reconstitution of the University of London we have at last a definite plan to lay before the public. It is a plan which has been drawn up by the Faculty of Medicine of the University, a body fully representative of medical education in the metropolis, and which has been officially adopted by the Senate of the University as an integral part of its scheme of future development. It is proposed to found as part of the University of London and under its direct control a public Institute of Medical Sciences to undertake teaching in physics, chemistry, biology, anatomy, and physiology for the purposes of medical students. The classes of the institute will not be limited to those only who are undergraduates of the University and propose to take its degrees. Provision will equally be made by the University for the instruction of students who are aiming at the College diplomas or the Licence of the Society of Apothecaries. Nevertheless, all who enter the institute will be studying in the University in fact as well as in name. They will be able to commence their career by entering directly at the University and until they have completed their classes in the institute they will not need, unless they wish, to join a hospital at all. They can wait till they have finished the academic part of the curriculum and select their hospital when the time has come for them to begin their clinical work. No compulsion will, of course, be exercised by the University over existing medical schools. Any that may find it to their advantage still to carry on the earlier as well as the later part of the curriculum will be at liberty to do so; those whose policy is otherwise will be able to receive their clinical students directly from the University of London Institute, as now they receive them from the Universities of Oxford and Cambridge and the University College of Cardiff. The University is willing and anxious to establish such an institute, but to do so funds are, of course, needed and funds for the purpose the University as yet has unhappily none. How much, it will be said, will be required? That has been the subject of careful estimate. Assuming the institute to be started, as contemplated, for 500 students at the outset, and assuming, as is not impossible, that a free site can be obtained, it is reckoned that £160,000 would be sufficient for the necessary buildings and equipment and that the annual expenses on staff and service would not exceed £20,000, of which about two-thirds would be recouped by fees, leaving to be provided from endowment between £6000 and £7000 a year, which brings the total capital endowment estimated as required to £375,000.

To what quarter is the University to look for this necessary sum? On the continent of Europe it would at once be recognised as a legitimate charge on the State. In our country that can hardly be. The tradition that professional education is no affair of the State is still deeply rooted in England. Even the modest subsidy annually granted by the Treasury to the English colleges is given under proviso that no portion of it shall be used for the purposes of the medical school. On State aid we can count but little. In America, if we may judge from the accounts lately brought back by the Mosely Commissioners, the matter would also be speedily settled. Our Chancellor would need but to sally out, pay some half dozen judiciously planned morning calls, exercise the persuasiveness which he is universally allowed to possess, and the thing would be done. Have we no wealthy men in London capable of being fired by emulation of transatlantic gifts to education, who will make this modest benefaction their peculiar care? As we lately learned with so much gratification, a most auspicious beginning at least has been made. May we trust that it will be followed by speedy fruition and that the list of subscribers already privately started will be covered without needless delay. Among them, one may safely predict, will be found not a few members of our own profession, but it must be clearly remembered and understood that it is no personal interest or advantage of the profession that is being sought. The object is, in the fullest sense, one of public concern, and it is to the public, not to the medical profession, that the appeal of the University is particularly addressed.

It would be a poor compliment to a university destined, as we hope, to a great academic position, to let it be supposed that this introductory work is all that the Faculty of Medicine will eventually expect from it. At present it is our most urgent need; but there are more ambitious fields of work awaiting the University later. The idea that the principal duty of a university is the education of undergraduates and that a bachelor's degree is the climax of a university career are among the fading traditions that the nineteenth century bequeathed to us. In the United States the more advanced school of educationists already begin to regard the teaching of undergraduates as but a secondary function of a university, if, indeed, they would admit it to be a university function at all. The preparation of candidates for initial degrees they are disposed rather to relegate to a class of institutions of subordinate rank which in America are called "colleges"; the real work of a university, it is argued by many, is that to which the attainment of an initial degree is only an introduction. "Graduate study," as Americans call it, is already with them a prominent feature of higher education and even seven years ago, according to the reports I have already quoted, 23 American institutions were able to make up between them a total of 4919 resident graduate students, an average of nearly 214 each. The medical world in England has long recognised the importance, and, indeed, the necessity, of graduate study and the number of members of our profession pursuing it in London in one shape or another would probably exceed anything that is to be found in America, but the provision which we have been able to make for it would, I fear, have to sustain a far less flattering comparison. It is certainly not yet so complete as to place any serious difficulty in the way of its absorption into the organisation of the University or to render the coöperation of a powerful university with it other than welcome. With the aid of the University we may perhaps one day see removed the weakness of the London system that has always been most apparent to foreigners—I mean the entire dependence of the academic position of a medical teacher upon the term of his hospital office, with the unavoidable result that some of our greatest clinicians have *ceased to teach at the very time when their experience is* ripest and their judgment is at its greatest maturity.

May I venture, in conclusion, to deprecate a certain note of impatience that occasionally makes itself perceived in the medical world because the development of our University is not proceeding at as rapid a pace as we could wish. We must not expect impossibilities. To make up the arrears of two generations in a great capital was as huge a task as any university could have had committed to it and some of the difficulties in the way have been very hard to surmount. That the constitution of our University is not an ideal one, that it may be open to the charge of cumbrousness, I, at least, am not concerned to deny; but machinery is of less importance than men, and we need not complain overmuch of a constitution that has committed the interests of our science to such strong and able hands as those of the representatives it has upon the University Senate and placed at the head of our Faculty a man so singularly capable as its present Dean of grappling with the difficulties of the present situation. The best compliment we can pay to the statesmanship and the self-sacrificing labours of Mr. Butlin and his fellow workers in our behalf is, I submit, to give them a patient as well as an earnest support.

The Goulstonian Lectures

ON

SOME DISORDERS OF THE BLOOD AND BLOOD-FORMING ORGANS IN EARLY LIFE.

Delivered before the Royal College of Physicians of London on March 8th, 10th, and 15th, 1904.

BY ROBERT HUTCHISON, M.D. EDIN., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL, ETC.

LECTURE III.[1]

Delivered on March 15th.

THE THYMUS.

MR PRESIDENT AND GENTLEMEN,—I have already remarked upon the prominent rôle played by the adenoid tissue amongst the blood-forming organs of early life and have discussed in general terms the probable reasons for its marked development. It was pointed out also that the mere fact of the extensive development of this tissue in the child and its great functional activity probably rendered it specially liable to become the seat of disease. It is to the study of the morbid processes which affect this tissue, a study which is full of difficulty and in which it must be admitted great confusion exists, that I have now to direct your attention.

Prominent amongst the local collections of adenoid tissue met with in the body and of special interest from the air of mystery which has always enshrouded its functions is the thymus gland. A study of the rise and fall of the functional importance of this gland may therefore be expected to throw some light on the functions of the adenoid tissue in general, for there can be little doubt, I think, that the thymus is not possessed of any functions peculiar to itself and distinct from those of the histologically similar tissues met with throughout the body, whilst, on the other hand, its compact structure and its unique situation render it peculiarly easy of study. In the human fœtus the thymus has attained the infantile type by the end of the third month of intra-uterine life, its development being brought about by a transformation of the epithelial cells derived from the hypoblast, and from this period onwards up to the time of birth it increases rapidly in functional activity, so that by the time when intra-uterine development is complete its weight relative to that of the body as a whole has reached its maximum point. From the moment of birth onwards it undergoes a steady decline which, however, is at first very gradual but after the second year goes on at an accelerated rate, although the gland is still possessed of some degree of functional activity up to the period when the growth of the body is complete. The following table from Friedleben's classical monograph on the thymus, indicates in a striking way the growth and decline of the gland:—

---

[1] Lectures I. and II. were published in THE LANCET of May 7th (p. 1253) and 14th (p. 1323), 1904, respectively.

Period of development.	Weight of thymus (in grans) to every pound of body weight.[2]
Third to fifth month of fœtal life	8·5
Sixth to seventh „ „	21·6
Eighth „ „	27·3
At birth	33·8
First to ninth month	23·5
Ninth month to second year...	22·7
Second to fourteenth years...	10·6

This decline in the growth of the thymus coincides exactly, as we have seen, with a steady diminution in the number of lymphocytes in the blood and may be taken, I think, as the index of a steady diminution in the functional activity of the adenoid tissue generally. We are here again brought face to face with the intimate relation which exists between the adenoid tissue and the growth and development of the body as a whole or in chemical terms with the rate of general metabolism. It is during the period when metabolism is most active that the thymus maintains its greatest weight, and I may suggest in passing that there may perhaps be found in this fact an explanation of the resumption of activity on the part of the thymus in such a disease as exophthalmic goitre, in which the rate of metabolism is usually increased, as well as of its tendency to persist in cases of gigantism and acromegaly.

I have said that the variations in the size and development of the thymus may probably be safely taken as indicating corresponding variations in the adenoid tissue as a whole. It would not be surprising if in a tissue so important as that which we are considering there were large room for the exercise of vicarious function, so that an over development of adenoid tissue in other parts of the body can take the place of the thymus and *vice versâ*. In favour of this view are the facts that the thymus may be entirely absent and yet growth be unimpaired (Friedleben) in which case presumably its functions are fulfilled by the adenoid tissue elsewhere. In favour of it also are the great individual variations in the size of the gland—variations which are not fully to be explained by mere differences in the body weight, which have struck all those who have made observations on the weight of the thymus at different ages. It is not improbable too that, as Mettenheimer has pointed out, the degree of development of the thymus at any given age varies in different countries and races which would be quite in harmony with the known variability in the rate of growth and development of the body under different conditions of inheritance and environment. In favour also of the vicarious replacement of the thymus are the results of observations on its experimental removal which show that no serious consequences to growth or development ensue, whilst the number of lymphocytes in the blood after the operation is increased rather than diminished, which is exactly what occurs after excision of the spleen and has been alleged by Ehrlich to be due to a vicarious over-activity of the lymphatic glands.

The great individual differences in the development of the thymus to which reference has already been made render it very difficult to be sure of pathological variations in its size. It was long ago shown by Friedleben that anything which interferes with adequate nutrition reacts with special force upon the thymus, so that its weight is notably lessened in starvation or after wasting diseases. The marked atrophy of the thymus in cases of infantile marasmus was first pointed out by Seydel. Hansen, Farret, and Mettenheimer went further and were inclined to regard the wasting of the gland as primary and that of the body as a whole as secondary, a view which has recently been insisted upon by Ruhrah and others.[3] Such a relationship, however, is very difficult of proof and against it is the fact that experimental removal of the gland is not followed by symptoms of wasting. In the meantime and until more convincing evidence has been collected it seems wiser to regard the atrophy of the thymus as associated with the diminution of growth and metabolism which accompany marasmus rather than as being the primary cause of the latter condition.

In discussing *hypertrophy of the thymus* we are again met with the difficulty of fixing upon a normal standard of development. Ruhräh gives the normal average weight of the gland during infancy as 18 grammes. Thursfield,[4] on the other hand, states that the normal weight is usually greatly exaggerated and that the average is between six and seven grammes. Observations on this point which have been made at the London Hospital for some time, but which are not yet ready for publication, tend to show that the weight of the gland varies very greatly in different children of the same age and that no constant ratio to the body weight can be shown to exist. Most observers are agreed, however, that an excessive development of the thymus is sometimes met with in which it may be increased to ten times the normal or more. The majority of such cases have been found, as is well known, in infants who have died suddenly with symptoms of asphyxia and to such cases the term "status thymicus" has been applied. Other writers who regard the enlargement of the thymus as merely a part of a general increase in the adenoid tissue throughout the body prefer to speak of the condition as the "status lymphaticus" or "lymphatism." The association of sudden death with enlargement of the thymus has long been recognised and many cases of it have been recorded but we are still quite in the dark as to the relationship of the enlargement of the gland to the occurrence of death. It would be going beyond the scope of these lectures to discuss this subject in detail, but as such cases, though not very uncommon, have received but scant attention in this country some of the leading views which have been put forward may be briefly indicated. According to one set of hypotheses the enlarged thymus in these cases acts purely mechanically either by direct pressure on the air passages or by interference with the vagus nerves or by exciting reflexly a spasm of the glottis. All these conjectures were subjected to severe criticism by Friedleben who concluded that none of them was tenable. There seems to be no doubt, however, that in some at least of the published cases there was distinct compression of the air passages and it has been suggested that a sudden throwing back of the head may, by vascular congestion, so increase the degree of pressure exerted by the enlarged gland as to induce asphyxia.[5] Such an occurrence would be comparable to the sudden death which may occur from the administration of an anæsthetic to a patient who is the subject of goitre. Nor can it be denied that spasm of the glottis may play a part in some at least of the cases, just as it occasionally produces sudden death in laryngismus stridulus though how the enlarged gland can excite such spasm is more difficult to explain.

According to the other leading view which has been put forward the enlarged thymus in these cases is not directly the cause of death but is merely an index of a general "lymphatic" dyscrasia which entails a general feebleness of resistance and renders the subject of it liable to sudden death from any cause. Several instances have occurred, for instance, whilst bathing. The very vagueness of such a theory puts it almost beyond the scope of criticism, but I may say that in at least one typical case I could find no increase of the adenoid tissue elsewhere nor any sign of impairment of health.[6] It certainly would be interesting to have an account of the state of the blood in these cases, particularly as regards the number of lymphocytes, but as enlargement of the thymus is almost impossible of diagnosis during life such observations are not yet forthcoming.[7] Of the other affections of the thymus I do not propose to speak, for they are for the most part identical with those to which all adenoid tissue is liable, whilst its comparative immunity to others, such, for example, as tuberculosis, is no doubt due to its not being in direct lymphatic connexion with any mucous surface.

AFFECTIONS OF THE LYMPHATIC GLANDS.

We now approach the consideration of a group of disorders in regard to which more doubt and confusion exist than in respect of perhaps any of the other affections of which I have hitherto spoken. The confusion to which I have referred is traceable to two causes: (1) to the adoption of a clinical classification based only upon the characteristics which can be observed at the bedside; and (2) to an inadequate study of the morbid histology of the affected organs after death. The adoption of a clinical classification would not be open to so much objection were it not that some of the most important criteria upon which such a classification if it is to be of any real value can alone be based have until recently been unavailable and are still too often omitted in the published reports of such cases. I refer especially to the information afforded by a careful examination of the blood. I need hardly point out that it is only within quite recent years that the importance of such examinations has been realised but for a long time it has been customary to label large groups of the cases about to be described with some name descriptive of their grosser clinical characteristics. Hence, an extensive nomenclature sprang up and was received into the text-books and made the basis of systematic descriptions and it is only now that we are beginning to realise how inadequate it is to our needs that names which were believed to indicate some one definite disease may really cover several different pathological processes and that our whole nomenclature requires to be reconsidered and recast. Now I think one may truly say that few things retard the advance of the scientific knowledge of disease more than the existence of a terminology which has ceased to have any real correspondence with clinical and pathological facts and we need not wonder that progress in the investigation of this branch of our subject has been made with but slow and faltering steps. If we think, for instance, of such terms as "lymphadenoma," "pseudo-leukæmia," "malignant lymphoma," or "lympho sarcoma," how vague and indefinite is the impression they convey! When an author describes a case under one of these designations how can we feel any certainty that the conception present to his mind is the same as that which the term employed arouses in our own? But it is hard to slough off outworn pathological creeds and in attempting to deal with these diseases I shall not have the presumption to suggest any brand-new terminology. I shall content myself with the humbler task of trying to give greater precision to some of the terms already in general use and with describing the clinical features and morbid histology of the pathological processes with which I believe them to correspond. Nor, it must be confessed, is the time yet ripe for a final classification, for any such to be of permanent value must be based, I take it, not upon the clinical features alone nor yet upon pathological histology but upon a knowledge of the particular morbific agency at work, of which both of these are but the expression. We await the progress of research to furnish us with this knowledge, and fortunately there are many signs that we are not likely to wait in vain. Meanwhile, in pursuance of the intention indicated above I turn to consider in the light of clinical and pathological observation that group of diseases which specially affect the lymphatic glandular system in early life. I propose, for the sake of greater clearness in this matter, to attempt no rigidly systematic order of treatment but rather to describe as briefly as may be some extreme clinical types of each disease and subsequently to consider the question of the relation of these to one another and the possible existence of intermediate forms.

[6] Diffuse overgrowth of adenoid tissue throughout the body has, however, been described by several observers in this condition.

[7] Ewing has found a lymphocytosis in one case.

1. Generalised Tuberculous Adenitis.

The first case to which I wish to direct your attention was that of a girl, aged 12 years, who was admitted into hospital suffering from anæmia with general enlargement of glands. The illness had begun eight months before with the appearance of a lump above the right collar bone. On admission she looked very anæmic; the glands were greatly enlarged in the neck, axillæ, and groins, being in some cases discrete, in others matted together. Neither the liver nor the spleen was enlarged, but there were some moist sounds over the right lung. There was distinct remittent fever which exhibited periodic exacerbations during which the glands became more enlarged and slightly tender. Examination of the blood showed 5,000,000 red cells per cubic millimetre with a decided reduction of hæmoglobin. The white cells varied in number at different examinations from 15,000 up to 70,000 per cubic millimetre and consisted mainly of the polynuclear variety. The patient went steadily downhill, developed signs of pressure on the bronchi, and died three months after admission.

Post-mortem examination showed that the glands were everywhere much enlarged and in part caseous, those in the mesentery being partly calcified. The tracheal and bronchial glands formed a large mass which had compressed the air tubes. There were some soft white nodules of the size of a bean in the right lung and in the muscular substance of the heart. The spleen was considerably enlarged and contained some white masses resembling infarcts. Sections of the glands showed a typical tuberculous structure and the presence of masses of tubercle bacilli.

A somewhat similar case was that of a boy, five years of age, who had suffered for six months from dyspnœa which seemed to ensue upon an operation for adenoids, prior to which he had enjoyed perfect health. He was markedly anæmic and had slight general œdema with effusion into the pleuræ and some ascites. There was enlargement of the glands in both sides of the neck and in the left axilla but the spleen could not be felt. There were signs of pressure on the right bronchus and some scattered patches of consolidation throughout the right lung. There was also a slight degree of irregular pyrexia. The blood exhibited the ordinary changes of a pronounced secondary anæmia along with a considerable polynuclear leucocytosis. Death took place from exhaustion, the case being regarded as one of lymphosarcoma. At the post-mortem examination, however, it was found that there was extensive caseation of the bronchial and mesenteric glands with patches of tubercle in the lungs and extensive ulceration of the intestine. The spleen was healthy. Tubercle bacilli were found in the glands in large numbers.

Such cases as these seem best described as examples of "multiple acute tuberculous adenitis." They are by no means common, but probably correspond to what used to be spoken of by the older writers as acute scrofula. Examples of such multiple glandular tuberculosis were described long ago by Hilton Fagge[8] and by Pye-Smith,[9] and a good example in a woman, aged 23 years, has been recorded by Francis Delafield.[10] More recent cases which may probably be referred to this group have been described by Hutschmann and Stross[11] and by Ferrarri and Comonotti.[12] The chief features of cases of this type are, I believe, these. They tend to occur especially in young subjects. They run a comparatively short course marked by irregular pyrexia often with periodic exacerbations. They exhibit more or less generalised enlargement of the lymphatic glands but not to any extent of the spleen and a pronounced degree of general anæmia accompanied by more or less polynuclear leucocytosis, the only exception to this rule that I am acquainted with being the case recorded by Ferrarri and Comonotti in regard to which it is stated that leucocytosis was absent. They may be regarded, I think, as examples of multiple infective adenitis, the infective agent being the tubercle bacillus.

Hodgkin's Disease.

Somewhat resembling the above in its clinical features, but totally distinct from them, I believe, is the following case:—

The patient, a girl, aged two years and two months, had suffered for a year from enlargement of glands in the neck. When she first came under observation she was markedly anæmic and hard discrete glands could be felt in the neck and groins but not in the axillæ. The liver was slightly enlarged. The spleen was two fingers' breadth below the costal margin and felt hard and nodular. There were some moist sounds over the lower lobes of both lungs and continuous irregular pyrexia. Examination of the blood showed 1,180,000 red cells and 5000 white cells per cubic millimetre. The red cells were very pale and unequal in size and a few normoblasts were present. A differential count of the white cells showed the presence of 51·5 per cent. of polynuclears 48 per cent. of uninuclear forms, and 0·5 per cent. of myelocytes. Death ensued from exhaustion without material alteration in the characters of the physical signs or blood, the case being regarded as one of tuberculosis.

The post-mortem examination showed great enlargement of the mesenteric and retroperitoneal glands, which on section were hard, pale, and glistening, with, in some, a few spots of caseation. The mediastinal glands were in a similar condition. The liver exhibited on its surface numerous white fibrous plaques which on section were seen to extend into the substance of the organ in the form of dense fibrous septa. The spleen showed the typical "hardbake" characters. The other organs were healthy.

Microscopical examination of the affected organs exhibited the entire absence of any tuberculous structure or of tubercle bacilli in any of the sections examined, but on the contrary the presence in a typical form of the changes presently to be described as characteristic of what for convenience we may still speak of as Hodgkin's disease.

In seeking to elucidate further the nature of such a case as this and to outline the features of the group to which it belongs we find ourselves on ground which has been, and still is, the arena of much controversy—controversy the issues of which have been much obscured by the nature of the terminology employed and by the neglect of that precise study of the morbid histology of the disease which I have already had occasion to deplore. It is doubtless in the knowledge of everyone here that the term "Hodgkin's disease" was first introduced into medical literature by Sir Samuel Wilks in a paper published in Guy's Hospital Reports in the year 1865 (vol. xi., p. 56). He applied it to cases similar to those already described by Hodgkin some years previously in his well-known paper entitled "On Some Morbid Appearances of the Absorbent Glands and Spleen."[13] The term, although a graceful and well-deserved tribute to the pathological acumen of Hodgkin, was, from a purely scientific point of view, an unfortunate one from the outset, for of the cases originally described by Hodgkin two at least were certainly not true examples of the disease now associated with his name. Cases more or less resembling in their clinical and gross pathological aspects those first described by Hodgkin were afterwards published on the continent in the same year as that in which Wilks published his paper and a French observer, Bonfils, showed that such cases were not attended by any increase in the white cells of the blood.[14] This absence of any increase of white cells in the blood formed such a marked distinction between these cases and those of so-called "lymphatic" leukæmia that Cohnheim in the year 1865 sought to emphasise the distinction by introducing into pathology the unfortunate term "pseudo-leukæmia,"[15] whilst three years later we find Trousseau in his ninety-first clinical lecture applying the term "adénie" to cases characterised by progressive enlargement of glands without blood change to mark them off from tuberculous and other glandular enlargement, cases of which, as he states, Hodgkin had already given a good description. Billroth[16] still further complicated matters by introducing the word "lymphoma," meaning thereby what Cohnheim meant by pseudo-leukæmia, but opposing it to the term "lymphosarcoma" which was employed by Virchow[17] and which Billroth wished to discard altogether or to restrict only to cases of true sarcoma of glands. Meanwhile the term "Hodgkin's disease" had come into general use in English literature, whilst "pseudo-leukæmia" found perhaps the greatest degree of acceptance on the continent. As clinical investigation became more accurate, however, and as the number of recorded cases increased, it began to be believed that in all probability more than one variety of morbid process was being so described and it is interesting to find Virchow declaring so long ago as 1892 that he had always regarded the term "pseudo-leukæmia" as a "Mischmasch," whilst in recent German writings there is a strong tendency to discard its use altogether and to substitute for it "malignant lymphoma" (Pappenheim) or "lymphomatosis" (Türk).[18]

[13] Transactions of the Royal Medical and Chirurgical Society, vol. xvii., p. 68, 1832.

It is refeshing to turn from these shifting quicksands of a changing nomenclature to the firmer ground of pathology, and, assuming that there is a group of cases which are characterised clinically by progressive enlargement of the lymph glands and sometimes also of the spleen without any increase of white cells in the blood—call them provisionally Hodgkin's disease or what you will—to ask whether such cases are marked by any characteristic morbid histology. Curiously enough, this aspect of the question has been largely neglected. While many have put on record cases, called them by one or other of the above names and described in some instances their gross morbid appearances, few have undertaken to give any accurate description of the histological changes met with in the affected structures. This omission has, however, been fully repaired in recent years (though the descriptions do not yet seem to have found their way into the text books) and that largely, one is glad to be able to say, by the labours of English and American workers. Even so far back as 1878 an extremely careful account of the histological characters of Hodgkin's disease was given by Professor Greenfield[19] in a paper read before the Pathological Society of London and published in its Transactions. He described the essential change as consisting in "a sort of chronic inflammation involving especially the fibrous stroma of the gland" and recognised the so-called soft and hard forms of the disease, the glands in the soft or early form being somewhat generally enlarged and the fibrous stroma appearing coarser than normal, whilst a large number of multinucleated cells containing from four to 12 nuclei could be observed adherent to the trabeculæ and often gathered into clusters where the fibrous change was progressing. In the more advanced—or what would be called by some the harder form—he found the glands practically converted into cicatricial tissue. He also described very carefully the characteristic histological changes in the spleen and the mode of their development. This description has been amplified but not in any important respect amended by the observations of subsequent workers. In a recent discussion at the Pathological Society on Lymphadenoma in its Relation to Tuberculosis[20] a very full description of the characteristic histology of Hodgkin's disease was given by Dr. F. W. Andrewes. He states that he has found the following changes: "1. The general plan of the structure of the gland is obscured and simplified; the distinction between cortex and medulla is abolished or nearly so, so that the whole gland has a more homogeneous appearance. 2. The number of lymphocytes is apparently very much decreased, they are proportionately scanty and no longer conceal the supporting framework of the gland. 3. In correspondence with this the framework has undergone hyperplasia, the fibrillar reticulum is conspicuous—its increase may amount to an actual fibrosis. The endothelial cells in connexion with it are more numerous and much more evident, here and there some of them attain a very large size and may contain two, four, or more large and deeply stained nuclei. These are the cells specially characteristic of lymphadenoma described by Virchow. ...... They may properly be described as lymphadenoma cells and though they are large multinucleate cells they have little resemblance to the giant cells met with in tubercle. They are not so large as the latter, they are more rounded and their nuclei, fewer in number, are larger. They stain more deeply and occupy a more central position; their protoplasm has less tendency to degenerative changes. 4. The eosinophile cells present in normal glands are always demonstrable in lymphadenoma, sometimes but not always, in vastly increased number."

Miss Dorothy M. Reed in a paper published in the Johns Hopkins Hospital Reports[21] has also dealt very fully with the minute anatomy of Hodgkin's disease. The microscopical changes, though apparently quite variable, always represent some stage in the same general process. In the earliest stage one finds only proliferation of the flat, so called endothelial cells which cover the reticulum of the lymph sinuses and of the large cells of the centres of the lymph nodes which are presumably identical with these. Mitotic figures in cells of this description are frequently seen. Dilatation of the blood-vessels and the lymph sinuses is usually a marked feature of the early stage. As the process advances we find the lymph sinuses and the reticular spaces filled with masses of lymphocytes and proliferating endothelial cells. The presence of these newly formed cellular elements destroys the normal appearance of the gland by obliterating the distinction between the follicles and the sinuses. The endothelial cells, which show many karyokinetic figures, form in proliferating large epithelioid cells with vesicular nuclei. Numerous giant cells with one or more nuclei and prominent nucleoli appear in great number. These give evidence in their structure and situation of being derivatives from the epithelioid cells and in places they are the most prominent feature of the specimen. As the process advances the connective tissue shows marked proliferation. The framework of the gland becomes increased and bands of connective tissue, starting often from about the vessels, gradually break up the gland substance into coarse lobules. This process takes place at the expense of the other cells and the tissue undergoes a fibrous transformation which may increase until the coarse bands of fibrous tissue are more prominent than the small cellular islands which they include. Large areas which can only be explained as anæmic necroses are frequently observed, the centres of which show completely degenerated cells with fragmented nuclei, whilst the surrounding connective tissue often exhibits hyaline transformation. It is evident, as Miss Reed points out, that a gland examined at varying periods in the process would appear very different to casual observation. In the early stages we have a very cellular tissue in which the predominating element is the lymphocyte. This represents presumably the soft type of the disease and we can understand why Hodgkin's disease is usually spoken of as a simple hyperplasia of the lymph gland. The fibrosis of the later stage represents the "hard type" and the connexion between the two is not at first obvious. The process in its early stage has been frequently confused with sarcoma and in the later stage with tuberculosis. She agrees with Dr. Andrewes in considering that eosinophile cells are usually present in great number in Hodgkin's disease but not invariably.

[21] On the Pathological Changes in Hodgkin's Disease, with especial reference to its Relation to Tuberculosis, 1902, vol. x., p. 133.

Enough has been said, I hope, to show that cases such as that which I have described above are associated with definite histological changes in the affected structures and we have now to discuss the nature of the pathological process by which these changes are brought about. Two hypotheses have been advanced in this connexion, one that the process is a malignant one, allied to sarcoma formation, and the other that it is "infective" in origin. Of these the latter, or "infective," view has now won its way to almost universal adoption and it would be superfluous to enter here and now into the arguments which have been advanced in its favour. Of the nature of the infective agent, however, we are still in ignorance. A few years ago there arose a strong inclination to regard the tubercle bacillus as the infective agent, Askanazy being one of the first to point out that tuberculous lymphoma might run the clinical course of a febrile pseudo-leukæmia. This view was strongly espoused by Sternberg and elaborately advocated in a paper in which he described the clinical characters and microscopical changes in 15 cases.[22] His position was for a time widely adopted[23] but recently a reaction against it has been manifest for which the more accurate histological studies of Andrewes,[24] Reed,[25] and Simons[26] are largely responsible. It is now recognised that the mere presence of tubercle bacilli in the affected glands in Hodgkin's disease as demonstrated either microscopically or by inoculation experiments is no proof that they are the *cause* of the changes found in the glands, whilst those who have most accurately studied these changes are convinced that they are quite distinct from those characteristic of tuberculous processes. It would seem that the subjects of Hodgkin's disease are specially apt to become infected secondarily either by the tubercle bacillus or by other infective organisms which may gain access to the lymphatic circulation, a circumstance which is not surprising when one remembers how greatly the number of lymphocytes in the affected glands is reduced by the overgrowth of the stroma, whilst it is to the lymphocytes in all probability that the arrest of casual infections is in normal conditions to be attributed. It is to such secondary infections most likely that the variability in the clinical course of cases of Hodgkin's disease and the intermittent pyrexial attacks which they often exhibit are due, whilst at the same time they are usually the immediately determining cause of the fatal issue of the disease.

Hitherto, it must be admitted, all attempts to trace the presence of any one infective agent have been baffled. Various organisms, pyogenic and other, have been isolated from the glands by different observers, but the claims of none to be regarded as the cause of the disease are supported by any overwhelming mass of evidence. It is possible, of course, that Hodgkin's disease is not really a definite pathological entity but represents merely the reaction of adenoid tissue to any mild chronic irritant present in the circulation of which the tubercle bacillus, possibly in an attenuated form, is merely one. But this, I need hardly say, is not a position in which pathological investigation can be content to rest, and towards identifying the true nature of the infective agent, if such there be, the efforts of future investigators must be directed. Meanwhile the term "Hodgkin's disease" must remain a purely clinical one, comprehending a group of cases which present certain symptoms and signs in common irrespective of the exact pathogenic agent at work in any given case. In future, however, if clinical and pathological observations are to advance hand in hand in unravelling this group of cases and in subdividing it into smaller groups in accordance with their causation more attention than hitherto must be bestowed on some points of clinical investigation. In particular we need more accurate descriptions of the condition of the blood in future cases and more frequent recourse should be had to the tuberculin test.

I have not so far discussed the question whether or not Hodgkin's disease is associated with any characteristic "blood picture." It has been customary to say that it is characterised by some degree of general anæmia—at all events in the later stages—but without any increase in the white cells. This, however, is not sufficient; we want more accurate information as to the relative proportions in which the different varieties of leucocytes are met with in cases of this group. In recent years a certain amount of attention has been devoted to this point and a considerable number of observations have accumulated but not yet sufficient to permit of any general statement being made. One set of writers, of whom Pinkus may be taken as the chief representative, maintain that Hodgkin's disease is characterised by a relative increase of the lymphocytes but others of equally high authority deny that this is the case, at all events invariably. Of seven cases described by Miss Reed[27] there was a relative and absolute increase of the small mononuclear leucocytes in two only, whilst in two other cases these cells were notably few in number; otherwise the blood counts were normal. And of ten undoubted cases (occurring at different ages) of which I have notes there was a polynuclear leucocytosis in two; in one both polynuclear and mononuclear forms were somewhat increased; in five the polynuclears were diminished—that is to say, the lymphocytosis was relative only; and in two alone was there a slight absolute lymphocytosis.

What we want to know is whether the occurrence of a polynuclear leucocytosis is only observed in those cases in which there has been a secondary infection, say with the tubercle bacillus. I am bound to confess that there was no sign of this, to ordinary naked-eye examination at least, in the two cases of my series in which the polynuclear cells were in excess but we want more information on the point. May such cases, perhaps, represent a special variety of the disease and be associated with a special infective agent? or does the relative numbers of the different cells present vary with the stage of the disease? Further, what is the relation of the blood picture to the size of the spleen? I have a general impression that there is a tendency for chronic enlargement of the spleen from any cause to be associated with a relative excess of lymphocytes in the blood, and if so is it only in those cases of Hodgkin's disease in which the spleen is markedly enlarged that such an occurrence is to be observed? To all of these questions no reply can be given until we are in possession of a sufficient number of cases which have been not only accurately observed during life but thoroughly examined after death. As regards the post-mortem examination of such cases I would urge the necessity of a microscopical examination of the bone marrow in every instance. In the whole literature of the subject there is, I regret to say, not a single paper with which I am acquainted which gives a description of the state of the histological changes in the bone marrow, if any, in this disease.

The other way in which future clinical observation might be made of greater service to pathology would be, as I have said, by making more frequent use of the tuberculin test. I am aware that here also we are exposed to the danger of fallacious conclusions. A positive reaction to tuberculin does not necessarily show, any more than the finding of tubercle bacilli in the affected glands, that the process has been to start with a tuberculous one, nor does the absence of such a reaction conclusively negative the possibility of tuberculosis being present. I cannot help thinking, however, that if such tests were made earlier and oftener the results would prove to be of great value. The worth of such observations would be greatly increased if at the same time a gland was excised early in the course of the disease for careful microscopical examination and, if necessary, for inoculation experiments. The ease with which local anæsthesia can now be induced has rendered the trivial operation which this would necessitate practically devoid of inconvenience to the patient and I now make it a rule to employ it in every case where no objection is raised. Were such observations made in a sufficient number of cases and early in the course of the disease we should soon be in a position to say definitely whether or not Hodgkin's disease is ever really tuberculous from the outset. I feel convinced that it is on such lines as these that our observations must be conducted in future if the clinician is to take his proper share in helping to elucidate the difficult problems of glandular disease.

As regards any light which may be thrown upon the nature of Hodgkin's disease by its incidence in childhood there is only this to be observed, that its period of maximum frequency certainly does not coincide with that of tuberculosis. Hodgkin's disease is, it is true, essentially an affection of early life. Of 43 cases recorded by Mitchell Clarke[28] ten were below the age of 10 years and 33 were below 40 years, and of 17 cases which were admitted to the London Hospital within the last two years two were below the age of 10 years and seven were below the age of 20 years. The disease, however, is certainly not one of infancy and whereas tuberculosis attains its maximum incidence in childhood about the second year, Hodgkin's disease is decidedly rare below the age of five years. I do not wish to attach undue importance to this point. We know too little of the factors which determine the age-incidence of disease to justify us in drawing any wide conclusions from such statistical observations alone, but at the same time any fact in the natural history of such an obscure affection as this is worthy of note. I have dealt rather fully with this matter and have gone, perhaps, somewhat beyond the legitimate scope of these lectures in thus discussing questions of general pathology, but it is only by taking a wide view of the problem that the best methods of solving it can be adequately presented.

deep purpl[illegible]
sinus was [illegible]
externally [illegible]
orbit. Th[illegible]

[illegible]

Such a case as this presents many points of interest. In the first place, I think, it must be regarded as an example of the soft form of lymphosarcoma, meaning by that a growth which begins in adenoid tissue, invades locally, spreads by the lymphatics but not usually (? ever) by the blood, very rarely forms true metastases and does not exhibit any tendency to degenerative changes (Kundrat[29]). The starting point in this case appears to have been in the retroperitoneal glands and the question arises, Were the growths in the bone examples of true metastases or were they due to a similar sarcomatous process starting in the adenoid cells contained in the bone marrow? The case resembles in many respects those of multiple secondary carcinoma of bone described by Frese[30] and others, particularly in the marked anæmia by which it was accompanied and which was of so profound a degree as to suggest at first a diagnosis of *pernicious anæmia* This no doubt was due to an extensive replacement of blood-forming tissue by new growth. The presence of a marked lymphocytosis is also of great interest. A similar occurrence was noted by Strauss[31]
[illegible] e closely resembled that
[illegible] ed multiple sarcomata of
[illegible] showed a leucocytosis of
57,600 per cubic millimetre, mainly mononuclear in type. The occurrence of some degree of lymphocytosis in cases of sarcoma seems to be not uncommon and would probably be found to occur more frequently if it were carefully looked for. Von Limbeck,[32] for instance, gives a table of cases of sarcoma in which such an occurrence has been observed, notably one of lymphosarcoma in which the white cells rose to 55,000 per cubic millimetre. The increase, he says, "is not wholly one due to the polynuclears but partly also to the mononuclears." It is in cases in which the bones are extensively involved, however, and in which the cells of the growth have direct access to the blood that one would most expect to meet with a lymphocytosis and such cases, if any, merit the designation "sarcomatosis of the blood." Mere periosteal growths, however extensive, do not appear to produce this effect. I have seen, for instance, three remarkable cases of sarcoma in the neighbourhood of the [illegible] attended by extensive periost[illegible] ch clinically closely resembled [illegible] t in none of these was there any increase in the lymphocytes of the blood and after death the bones were found not to have been invaded. The diagnostic value of lymphocytosis will be referred to immediately.

RELATIONS OF THESE PROCESSES.

I have described multiple tuberculous adenitis, Hodgkin's disease, and lymphosarcoma as types of three pathological processes affecting adenoid tissue in a primary and widespread fashion and the further question now arises are these entirely distinct or do intermediate or mixed pathological types occur? As regards the question of tuberculous adenitis and Hodgkin's disease I have already expressed the opinion that these are entirely distinct and separate and that each of them is characterised by its own peculiar morbid histology. It has also been indicated, however, that glands which have been primarily affected by Hodgkin's disease may become secondarily the seat of tuberculosis and that it is to such secondary or terminal infections that much of the confusion which has hitherto prevailed regarding the identity of Hodgkin's disease is to be attributed. It was also pointed out when discussing the nature of the latter disease that it was possible that it might sometimes be produced by a peculiar and possibly attenuated tuberculous infection, though of this no convincing proof has yet been brought forward. On the other hand, between Hodgkin's disease and lymphosarcoma there is, I believe, no relationship. The morbid histology of the former is quite distinct from that of even the more fibrous forms of lymphosarcoma such as are met with in the mediastinum. Lymphosarcoma is often, though not always, attended by an absolute lymphocytosis which may reach quite a high degree, whereas the lymphocytosis of Hodgkin's disease, though also inconstant, is at best merely relative and due not so much to an absolute increase of lymphocytes as to an absolute reduction in the number of the polynuclear forms. To class Hodgkin's disease and lymphosarcoma together under the title of "lymphomatosis," as some German writers propose to do,[33] seems to me, therefore, reactionary and calculated to retard our real knowledge of each disease and is to be attributed mainly to a failure to recognise the characteristic morbid histology of Hodgkin's disease which has been established by the labours of English and American workers.

When we turn to consider a possible relationship between the diseases just described and the leukæmias dealt with in the last lecture we are on more uncertain ground. In discussing the use of the term "pseudo leukæmia" as a substitute for "Hodgkin's disease" I had occasion to point out what confusion it had caused. This confusion is largely due to the fact that such a term as pseudoleukæmia suggests a relationship of Hodgkin's disease to leukæmia which has no foundation in fact. In this connexion much misapprehension has been brought about, in my judgment, by the exaggerated importance ascribed by some writers, notably by Pinkus, to the supposed lymphocytosis of Hodgkin's disease. Now lymphocytosis, whether absolute or relative, is, as we have seen, by no means a constant phenomenon in Hodgkin's disease. That cases of true lymphatic leukæmia do occur in which, at one stage of the process at least, there is no *absolute* increase of the total leucocytes must be admitted but in such cases there is notwithstanding a marked absolute increase of lymphocytes, whilst the normal total count is due to a great reduction of the polynuclear forms. The supposed analogy between the blood pictures of the two diseases is therefore fallacious. In addition to this the morbid histology of the two processes is totally distinct, lymphatic leukæmia being a disease which affects only the parenchyma of the glands and adenoid tissue generally, whereas in Hodgkin's disease it is the supporting tissue which is mainly involved. Further, I have met with no case in my own experience either in the child (in whom, as we have seen, lymphatic leukæmia is relatively rather frequent) or in the adult, in which leukæmia appeared to pass into Hodgkin's disease or *vice versâ*, nor have I found any record of such a case in my reading. I think we may safely conclude, therefore, that between Hodgkin's disease and leukæmia there is no relation and that the two diseases belong to totally different orders of pathological processes. I may appear, perhaps, to have laboured this conclusion overmuch, for I doubt not that in this country at least few would be found to demur to it, but one feels bound to protest against the attempts which are being made on the continent to bring so-called pseudo-leukæmia and lymphatic leukæmia together and to look upon them as differing in degree only and not also in kind.

Between lymphatic leukæmia and lymphosarcoma, on the other hand, the possibility of a certain relationship is not so easily to be dismissed. Lymphosarcoma certainly possesses several points of resemblance to the more chronic forms of lymphatic leukæmia. In both we have to do with an overgrowth of the parenchymatous elements of the adenoid tissue, the difference being that in one case (leukæmia) the overgrowth is restricted to the organ primarily involved, whereas in the other (lymphosarcoma) it breaks through into surrounding tissues. The blood picture of the two diseases may also present very similar features. In both there is a profound general anæmia with an absolute increase of lymphocytes which is constant and of high degree in leukæmia, less constant but often very marked in lymphosarcoma. It is probable, however, that the lymphocytosis never reaches the same degree in lymphosarcoma as it does in typical lymphatic leukæmia unless, or indeed even when, the sarcomatous process has started in, and extensively involves, the bone marrow, though on this point we want further information, whilst the locally invasive character of lymphosarcoma marks it off quite definitely from any true lymphatic leukæmia.

One finds a connecting link between the two processes, however, in the disease termed "chloroma." This we may define with Günbel[34] as consisting of multiple green lymphomata localised chiefly in the periosteum and neighbourhood of the bones, especially of the head, and the loose connective tissue along the spinal column, accompanied by hyperplasia of the whole lymphatic apparatus, by lymphoid transformation of the bone marrow, and by a blood picture similar to that of lymphatic leukæmia. In its seat of election this disease presents a close resemblance to such a case of lymphosarcoma as that described above, though with less tendency to local invasion, for the lymphomatous growths of chloroma tend merely to "soak," as it were, along the lines of least resistance, such as the subcutaneous and subperiosteal tissues, rather than actively to invade neighbouring organs, whilst in its affection of the marrow and in the blood picture of which that is merely the reflection it presents a closer resemblance to lymphatic leukæmia. The latter resemblance is rendered still more close by the fact that cases of apparently pure lymphatic leukæmia are occasionally met with in which the enlarged glands exhibit the greenish colour usually regarded as characteristic of chloroma. Of this a well-marked example recently occurred in the London Hospital and others have been recorded by Byrom Bramwell[35] and Lindsay Steven.[36] We have thus, it would seem, in lymphosarcoma, in chloroma, and in lymphatic leukæmia three closely allied processes exhibiting a descending scale of malignancy but presenting many features in common and in the case of chloroma and lymphatic leukæmia at all events possibly tending to pass into each other. Of these lymphatic leukæmia is often met with in infancy, chloroma is more characteristic of childhood and adolescence, whilst lymphosarcoma tends to occur rather in the later periods of life.

I have now passed in review the most outstanding of the disorders which affect the blood and blood forming organs in early life and it may be well for us to cast a glance back over the ground which we have traversed and to survey it for a moment as a whole. It will have been observed that the blood disorders of early life differ from those of more mature years mainly in exhibiting less definition of type. Such comparatively clear-cut disorders as pernicious anæmia, chlorosis, and myelogenous leukæmia—disorders, in a word, of the bone marrow—occur rarely, if at all, in infancy and early childhood, whilst several secondary anæmias and infective leukæmic and sarcomatous processes affecting adenoid tissue are relatively common. Peculiar to infancy is one type of anæmia only—namely, that which I have spoken of as anæmia splenica infantum, a variety which is in close relationship in its slighter degrees to the secondary anæmias, whilst in its severer manifestations it approximates to the type of the leukæmias. This affection, indeed, epitomises in itself all the peculiarities of the anæmias of infancy, exhibiting on the one hand the marked destruction of red cells with the ready appearance of nucleated forms which characterises the severer secondary anæmias of this age, whilst on the other it shows by the tendency for the non-granular cells in the blood to be increased that reaction of the adenoid tissue to unfavourable influences which is a striking peculiarity of childhood. The ease with which secondary anæmia develops in early life we have seen to be due in part to great vulnerability of the blood cells and in part to the poverty in hæmoglobin which seems to be natural to this period of life, whilst the special character of that anæmia—namely, the readiness with which normoblasts appear in the blood stream—may perhaps be ascribed to the restricted area of the red cell forming tissue possessed by the infant. It must be remembered, also, that to many influences specially destructive of blood or inimical to its formation the period of infancy is peculiarly exposed. Amongst such influences are defective diet—in particular a diet deficient in proteids and in iron—chronic gastro-intestinal disorders, the syphilitic cachexia, and various infective processes with their resulting poisons. The tendency for the adenoid tissue to react in all the severe anæmias in infancy, with the consequent appearance of an excess of leucocytes in the blood stream, I have tried to correlate with the extensive development of that tissue in the first two or three years of life and with the active functions which it appears to discharge. The nature of these functions were briefly discussed, it will be remembered, and the suggestion was made that the activity of the adenoid tissue may be related to the processes of nutrition and growth. This very activity and extent of the adenoid tissue, moreover, seem to render it specially obnoxious to infective, leukæmic and malignant processes, whence the frequency of Hodgkin's disease, lymphatic leukæmia, chloroma, and lymphosarcoma in the earlier years.

At various points throughout these lectures I have had occasion to comment upon the absence of sharp differentiation between the different types of anæmia in early life. It was shown that the splenic anæmia of infancy tends to fade off at the lower end of the scale into the severer forms of secondary anæmia and at the upper into the leukæmias. It was pointed out, too, that forms of anæmia occur in early life which partake of the characters both of the lymphatic and of the myelogenous type, whilst between lymphatic leukæmia, chloroma, and lymphosarcoma fixed boundaries can hardly be drawn. This indefiniteness of type, it has been suggested, may be merely the reflection of an equal want of definition in the function of the various blood-forming organs in early life and of an incomplete division of labour amongst them. At all events, it may well be that, even although the differentiation of function on the part of the blood-forming organs in infancy is fairly complete in health, yet under adverse conditions a reversion may take place more easily than in the adult to the primitive conditions which obtain in the fœtus. In these circumstances the territorial distinctions tend to be lost, the mother-cells of the bone marrow (myelogonia) no longer producing merely myelocytes and those of the adenoid tissue (lymphogonia) lymphocytes, but both myelogonia and lymphogonia combining to produce that species of cell the demand for which in the blood stream is greatest at the moment. It is in this direction, I believe, that further study of the blood disorders of early life is likely to lead to results which will materially modify our conceptions as to the processes of blood formation in general.

In conclusion, I would say that no one here can feel more acutely than myself the many shortcomings of these lectures and how unworthy they are of this audience and this place. I have tried to deal with a subject of great difficulty and often of great obscurity and in looking back I fear that I have been able to illuminate it but little I shall not have wholly failed, however, if I have succeeded in bringing into clearer prominence the peculiar nature of the problems presented by a study of the blood disorders of early life and in suggesting lines of fruitful work for future investigators. In any case I can only hope that the kindness which called me to this position, for which I wish to return my sincere thanks, will be equal also to the task of overlooking the poverty of my efforts to fulfil its obligations.

the rupture had reappeared when he was brought to the hospital. At the operation the sac contained a very little fluid. About six inches of small intestine had been suddenly expelled from the abdomen, the amount expelled causing immediate and tight strangulation of the loop. The intestine was full of blood, showing that the occlusion of the vessels had not been complete at once. The blood within the bowel had absorbed all the intestinal gases. Owing to the distension of the coil of gut it had twisted on itself, completely occluding everything. The gut itself was thin, sticky, and inelastic; not œdematous, doughy, or offensive. The vessels in its mesentery were thrombosed. About a foot of gut was removed, the resection being most free above the obstruction. An end-to-end anastomosis was made with two layers of continuous silk stitches. The testis was underneath the gut and had a half twist on its spermatic cord. The gland was excised. A radical cure was performed with fine salmon gut. On the second day an enema yielded a good result of flatus and on the fourth day another enema gave a large fæcal result. Feeding by mouth was begun on the fourth day. Healing per primam ensued.[3]

When once this necrotic, necrobiotic, or necrogenous process gets a good start it may extend, especially up the bowel in the part above the constriction. I have already mentioned and illustrated this tendency to extend in the St. Thomas's Hospital Reports, 1900. It is not easy to find records of cases in which gangrene has occurred after resection, as in hospital reports they escape notice and surgeons do not publish them themselves. Nevertheless, Mr. Hewston has recorded one in a woman, 65 years of age, for whom he resected the small gut in a right femoral hernia which had been strangulated four days. The resection had been to all appearance free. But post mortem the bowel was gangrenous for an inch above the line of suturing. There is no record of a case in which the gangrene spread downwards to any extent sufficient to cause any trouble in treatment. It is important that the surgeon should bear in mind this pathological point. Professor Kocher of Berne some years ago pointed out that it is not the amount of gut resected which kills the patient. It might almost be added that it is usually the insufficient resection of the gut which causes the fatal result, an anastomosis having been performed on tissues which were teeming with organisms. Mr. A. E. Barker[4] strongly advocates a wide resection. Mr. Makins in the Transactions of the Clinical Society for 1903 has advocated rather extensive involution of doubtful bowel wall in these cases. And later it has been emphasised by Dr. Crampe[5] of the Königsberg Klinik. This is a most suitable and successful measure in appropriate cases, as both have shown. But its applicability diminishes as the action of micro-organisms over the results of interference with the blood-supply increases. Therefore it will be inapplicable in cases in which gangrene has occurred within a few hours of, or shortly after, the onset of strangulation, whilst it will be most suitable in patchy gangrene about the site of the constriction of the gut and not in œdematous parts of the loop. It is a measure far more applicable to doubtful pieces of gut, as Dr. Crampe has urged, rather than those in which gangrene has already declared itself.

MECKEL'S DIVERTICULUM.

In the foregoing sections of this lecture it has been pointed out that the appendix forms the terminal portion of our great natural intestinal "backwater," the cæcum. Any diverticulum of the intestine forms a cul-de-sac and a somewhat similar backwater. The most constant diverticulum of the human intestine is that described by Meckel which represents the proximal part of the duct connecting the intestine and the yolk sac of the fœtus. This little process arises from the ileum about 30 inches from the ileo-cæcal valve and is present in 2 per cent. of subjects. It differs from the appendix in several most important features which naturally cause the differences in the pathologies of the two tubes. For instance, Meckel's diverticulum is not situated at a place utilised by the products of digestion as a "rest," as the appendix is at the cæcum; its lumen is almost invariably as large as that of the intestine from which it springs, and it is, as a result, well flushed out by the flow of the intestinal fluids caused by the peristalsis of the ileum as well as by its own contractions. There is therefore no stasis of the fæcal contents within the diverticulum nor the opportunity for organisms to luxuriate within it to the same extent as is the case with the appendix. Therefore it is not to be expected that the former will suffer from as many, or perhaps as acute, inflammations as does the latter. These analogies and homologies interested me so thoroughly that an attempt was made to ascertain all the cases in which this blind process of bowel was diseased. The results have repaid the labour and as they have never been collected previously they are briefly reproduced. In all, I have extracted from hospital reports and literature over 300 cases which are arranged in a table (Table IV.).

TABLE IV.—*Diseases of Meckel's Diverticulum.*

Cystic formation, retention cysts	7 cases.
Tuberculous disease...	3 ,,
Typhoid ulceration	4 ,,
Chronic inflammation (diverticulitis)	3 ,,
Acute inflammation (diverticulitis)	3 ,,
Ditto, with necrosis or gangrene	11 ,,
Ditto, with perforation	16 ,,
Ditto, with local abscess	3 ,,
Torsion of the diverticulum...	5 ,,
Fistula at the umbilicus	20 ,,
Prolapse at the umbilicus	15 ,,
Intussusception	23 ,,
Foreign bodies in the diverticulum	11 ,,
Diverticulum ruptured by a kick	2 ,,
Intestinal obstruction caused by the diverticulum (other than intussusception) ...	166 ,,
Ditto and volvulus (?)	3 ,,
Ditto and perforation	6 ,,
Volvulus (?)...	1 case.
Papillomata	12 cases.
Carcinoma	1 case.
Total	315 cases.

The above list, although it gives all the records that could be found, has the disadvantage of minimising the frequency of the more common affections and magnifying that of those of rarer occurrence. By means of reducing the above catalogue to shorter proportions and giving percentages instead of absolute figures a better idea of the relative importance of the various factors may be gained (see Table V.).

TABLE V.—*Diseases of Meckel's Diverticulum.*

Intestinal obstruction other than by intussusception	56 per cent.
Inflammation, or diverticulitis (American) ...	13 ,,
Fistula, prolapse at the umbilicus	11 ,,
Intussusceptions	7 ,,
The rest	13 ,,

In the case of this diverticulum the cases described as due to inflammation or diverticulitis (American) bear to those in which the process caused intestinal obstruction other than by invagination the proportion of 1 to 4. In the case of the appendix inflammation is exceedingly common, whilst it is rare for that organ to form a band and to cause obstruction. This great difference is due to the previously mentioned factors which have led to the comparative infrequency of inflammation in the diverticulum and its situation amongst the coils of small intestine which it can easily ensnare and obstruct. But the difference in the relative frequency or infrequency of inflammatory processes in the appendix and the diverticulum is more apparent than real, as the following problem will show, and at the same time teach us to recognise a new and, when the diverticulum is present, a very common disease. For practical purposes the intestinal obstruction caused by Meckel's diverticulum may be regarded as due to the ensnaring of a loop of bowel beneath the process which is adherent by its tip. The regions in which the adhesions have been described are given in Table VI.

TABLE VI.—*Adhesions of Meckel's Diverticulum.*

To the umbilicus	23 cases.
,, ,, anterior abdominal wall	7 ,,
,, ,, posterior ,, ,, ...	,,
,, ,, mesentery	40 ,,
,, ,, omentum	5 ,,
,, ,, small bowel	7 ,,
,, ,, bladder	1 case.
,, ,, femoral canal	1 ,,
,, ,, pelvis	2 cases.
Total	90

[3] This case was read to the South Hants branch of the British Medical Association at Winchester, 1902, under the presidency of Mr. David Browne.

[4] The Lancet, June 6th, 1903, p. 1576.

[5] Beiträge zur Klinischen Chirurgie, Band xxxviii., Heft 3, 1903.

The diverticulum is recorded as being without adhesions in 39 cases but doubtless this condition is not mentioned as often as the presence of the adhesions is because the latter are so frequently the source of trouble, so attracting attention. The question may be well asked, What are the causes of these adhesions? In the first place they may be divided into two kinds, those due to errors of development and those due to inflammation. In the former the process may open at the umbilicus, be connected with it by a cord containing merely the remains of the vitelline vessels, or again, as my friend Dr. S. G. Scott of Leeds has told me, the connexion with the anterior abdominal wall may contain the remains of the same structures. The latter class of case may be due to an error of development, inflammation, or both. But for my purpose they will be considered as being of developmental origin in order that the error, if any, be made on the safe side for my purpose—i.e., of finding too many developmental fixations. The second class of cases arise from inflammatory causes, such as the adhesions to the mesentery, omentum, small bowel, &c. The inflammation or diverticulitis is due to the causes inherent to an intestinal "backwater," as exemplified in an acute degree in the diseases of the appendix, and in a subacute degree those of Meckel's diverticulum. Placing these two classes side by side it is seen that developmental adhesions formed in 30 cases, or 33 per cent.; and pathological adhesions formed in 61 cases, or 67 per cent. The figures emphasise the frequency of what may be called a chronic or subacute diverticulitis—a disease hitherto unrecognised yet far-reaching in its consequences.

Many are the points of interest connected with the pathology of this diverticulum, but there is not time nor, indeed, is this the proper place to enter upon such a dissertation. To return then to the subject of these lectures, acute infective necrosis, 30 cases of perforation and sloughing of the diverticulum have been recorded. As is the case with the appendix the perforations usually occur at the tip—i.e., at the part least completely evacuated. Though in the case of the diverticulum it frequently has a direct blood-supply. These cases are always diagnosed clinically as appendicitis. No primary vascular lesions have been described. The perforations found in Meckel's diverticulum, which have been recorded, exhibit one very marked difference from those found in the appendix—namely, their multiplicity. Mr. Makins described a case[6] with numerous small perforating ulcers of the diverticulum. In the appendix it is very rare that more than one has been seen; in the stomach and duodenum two have been described, very rarely more. It is not easy to explain this peculiarity on the part of Meckel's process.

In the appendix the infection is gross on account of the host of organisms present and the inability of the tube to contract efficiently and to relieve itself of them. In the case of the diverticulum there are probably not the number of organisms present, and, again, this tube can evacuate itself. It would seem that in the appendix the organisms are in the lumen of the tube and in the diverticulum they are imprisoned in the glands, otherwise they would be washed away. Hence in the former the gangrene or necrosis is gross and in the latter it occurs in small, numerous punctate patches. A similar explanation may account for the pinhole perforations occasionally seen in the stomach, duodenum, &c.

Five cases of torsion of Meckel's diverticulum have been recorded, the most extensive gangrene having occurred within 24 hours of the onset of symptoms, whilst the cases have been clinically of the most fulminating type. In the most severe instances there may have been both interference with the blood-supply and the action of virulent micro-organisms. Mr. T. Carwardine[7] has recorded a unique and interesting case which is reproduced shortly.

Case of torsion of Meckel's diverticulum leading to the formation of a retention cyst in a fœtus.—Mr. Carwardine operated upon a male child, two days old, for intestinal obstruction. He found a large meconium containing cyst of Meckel's diverticulum separated from the ileum by three complete twists which had also obstructed the latter. The torsion must have begun in fœtal life and it was unaccompanied by any signs of inflammation or necrosis in the cyst.

This case is unique as it stands but it possesses additional interest from the point of view of acute infective necrosis or gangrene. Before birth the meconium is sterile and consequently Mr. Carwardine's case becomes an exceedingly rare example of an aseptic torsion of the bowel. Hence the absence of gangrene and signs of inflammation. To form a contrast with this very rare aseptic and, in a local sense, pathologically mild condition, examples are given of two of my own cases in which there was acute infective necrosis of both the diverticulum and the loop of ensnared bowel in intestinal obstruction. The possibility of the occurrence of this double gangrene in the most common form of clinical manifestation caused by this process—namely, intestinal obstruction, which was present in 56 per cent. of all cases—emphasises the importance of the lesions illustrated.

Case of intestinal obstruction by an adherent Meckel's diverticulum; acute infective necrosis or gangrene of the diverticulum and of the ensnared intestine; death.—A male, aged 32 years, was admitted on July 28th, 1901, into St. Thomas's Hospital with the history of three days' acute intestinal obstruction. The abdomen was opened and the obstruction was found to be caused by a diverticulum of the ileum about four inches along and adherent by its tip to the mesentery of the small bowel. Underneath this band a coil of small gut was strangulated and also had twisted on itself, so completing the obstruction. The diverticulum itself was sloughing and was removed, the bowel was tapped and sutured, followed by lavage, &c. A day later the lower segment of the wound was reopened and the ensnared coil was found to have become gangrenous. It was pulled out of the abdomen and Paul's tubes were inserted. Death followed in a few hours.

Case of intestinal obstruction by Meckel's diverticulum; infective necrosis of the diverticulum; post-operative mesenterial thrombosis and necrosis of the strangulated loop; peritonitis; death.—A boy, aged ten years, was sent to St. Thomas's Hospital on Feb. 3rd, 1904, with signs of peritonitis and intestinal obstruction of four days' duration. At the operation the cause of the obstruction was found to be that a coil of small bowel had become ensnared beneath an adherent diverticulum and twisting on itself. The adhesion was to the mesentery of the small bowel. The peritonitis was found to have arisen in part from a perforation of the small bowel at the site of constriction. The diverticulum was constricted over the ensnared loop and its tip was converted into a nearly free gangrenous cyst. The process was removed and the perforation was sutured. The boy died 48 hours later from peritonitis. At the post mortem examination it was found that the vessels in the mesentery of the ensnared loop had become thrombosed; they were not so at the operation, as this point was especially looked for in view of the post-operative necrosis in the previous case. The thrombosis had spread to the vessels in the mesentery of the ileum below the diverticulum. As a consequence the necrosis in the loop which had been strangulated had extended downward nearly as far as the cæcum. About four feet of bowel were gangrenous at the post-mortem examination.

This case illustrates the post-operative thrombosis of the mesenterial vessels, which was most probably of bacterial origin, the consequent necrosis of the coil which had been ensnared, and the extension of the necrosis downward in the gut with the thrombosis. The gangrenous cyst, half an inch in diameter, at the tip of the diverticulum would very shortly have become separated, and in so doing would in all probability have freed the adherent constricting band and relieved the mechanical obstruction. The case might then have been regarded as a primary necrotic inflammation of the diverticulum. It is almost tempting to suggest that some of the reported cases may have been of such an origin. The idea does not seem to have suggested itself to authors who have written on this subject.

EPSOM COLLEGE.—Dr. C. Holman, treasurer of Epsom College, has asked us to make public the following acknowledgments. The London and Counties Medical Protection Society, Limited, has voted the sum of £26 11s. 6d. to the funds of the Epsom College Royal Medical Foundation. A donation of £25 2s. 10d. has been received from the St. Andrews Graduates' Association, being one-half of the balance in hand at the dissolution of that body. A donation of £10 10s. has been received from the Wimbledon and District Medical Society and an anonymous donation of £25 per Messrs. Coutts and Co.

SOME EXPERIENCES IN THE SURGICAL TREATMENT OF SUPPURATIVE LESIONS OF THE NASAL ACCESSORY SINUSES.

BY HERBERT TILLEY, M.D., B.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE, W.

DURING recent years it has become a well-established fact that a discharge from one of the nasal accessory cavities not only produces well-marked local changes productive of certain definite and troublesome symptoms referable to the diseased areas, but also that the same discharges exercise an evil influence upon the general health and well-being of the patient. These remoter symptoms have been supposed to be due to absorption of septic products which have been swallowed into the stomach and to such causes have been ascribed by Dr. William Hunter certain forms of septic gastritis and some of the graver forms of anæmia. The effect of such absorption upon the higher nerve centres is also well known to those who have to deal with the type of case to which I am about to refer and it reveals itself in a variety of ways. Such statements as "my brain seems in a fog," "constant feeling of weight in the head," "no energy," "frequent depression," and "inability to concentrate the attention," are favourite expressions by which such patients endeavour to describe their feelings. Although the local and general symptoms are well known to those who have given some detailed attention to the diseases of the upper respiratory tract, yet one has reason for believing that to the general body of the profession both the local and more remote symptoms of chronic suppurative lesions in, and around, the nasal cavities are very frequently either not recognised at all or are honoured with no greater evidence of diagnostic skill than is conveyed by that useful term "chronic nasal catarrh."

It has therefore seemed to me worth while to select a few typical cases which have recently occurred in my practice and to use them in illustrating some of the chief symptoms, the diagnostic features, and the method of treatment of some of the commoner suppurative lesions of the nasal accessory sinuses. In order to avail myself of accurate details as to the symptoms, treatment, and more especially of the result of the latter, I propose to make a selection from a series of cases which came under my private notice during last year (1903). During those 12 months there came before me 52 cases of antral suppuration (four acute and 48 chronic), 15 of combined chronic suppuration of the frontal, ethmoid, and antral sinuses, and four in which the sphenoidal sinuses were simultaneously affected with one or more of the last-mentioned group. While the exigencies of space will necessitate the omission of all except the chief points in diagnosis and the main details of treatment, it may yet be hoped that a careful study of the histories of the patients will enable the reader to recognise the nature of such cases when he meets them and thus ensure the first step in enabling him to treat them with success provided only that he has mastered those technical details which are absolutely essential for the efficient examination and treatment of diseases of the upper respiratory passages.

CASE 1. *Acute inflammation of the maxillary antrum.*—The patient, a man, aged 41 years, was seen on April 14th, 1903. He had suffered from pain in the left cheek and over the left eye for five days. The temperature ranged between 99° and 101° F. On the third day a profuse discharge of foul pus flowed from the left nostril and the pains were considerably lessened. Examination of the left nasal cavity by reflected light showed the nasal mucosa to be very congested (compared with the right side) and yellow pus could be seen in the left middle meatus. The canine fossa was tender on deep pressure. On placing a six-volt electric lamp in the patient's mouth and darkening his surroundings the cheek area below the left eye was darker than on the right side. The second left upper bicuspid was "dead." Under "gas" anæsthesia this tooth was removed, the alveolus was perforated in the position of its buccal root, and a silver wire alveolar drainage-tube was inserted. The patient syringed out the antrum twice daily with warm boric lotion for three days, then once daily for three days, next once on alternate days, and finally when irrigation brought away no pus he removed the tube entirely. No recurrence had taken place when the patient was last seen in April, 1904.

The above is a typical instance of acute suppuration of the antrum arising from septic inflammation around the root of a neighbouring tooth. The abscess had burst into the antrum. The case illustrates the rapidity with which the antral mucous membrane can recover itself if the source of septic infection be early removed. The recovery will be hastened by free drainage and irrigation with a warm, mild antiseptic lotion or even with simple normal saline solution.

CASE 2. *Chronic antral suppuration.*—The patient, a single woman, aged 29 years, was seen on May 5th, 1903. A history of 11 months' "stuffiness" in the left nostril and constant suffering from "nasal catarrh" was given. There was an occasional discharge of yellow matter from the nose which smelt like "bad drains." Neuralgia over the left eye was often noticed in the early morning but it passed off by 11 or 12 o'clock. Examination of the left nasal cavity by reflected light showed a canary-yellow discharge in the left middle meatus, the anterior end of the middle turbinal was swollen and red, and the mucosa in the middle meatal region was very œdematous. The purulent discharge was now removed with wool mops and the patient's head placed in such a position that the left cheek pointed upwards; in two minutes the discharge had reappeared in the middle nasal meatus. Transillumination by electric light (*vide* Case 1) gave the same result as in that case. To make certain that the pus came from the antrum a fine sharp-pointed cannula was introduced into the left nostril and passed backwards and outwards to pierce the inner antral wall below the attachment of the inferior turbinal bone. By affixing a syringe and injecting some warm salt water the returning fluid brought away a large quantity of foul pus. Under "gas" anæsthesia the carious second upper left bicuspid and the first molar teeth were removed and an alveolar drainage tube was inserted as in Case 1. Irrigation with a mild antiseptic lotion was ordered. Writing in April, 1904, the patient says that the headaches had disappeared and that the amount of pus had decreased and its fœtor had quite vanished, but a certain amount of purulent matter was still secreted in spite of frequent changes in the nature of the irrigating lotions.

The above is a common type of case which generally sails under the false flag of "nasal catarrh." The continuance of the discharge is almost certainly due to chronic degenerative changes in the lining mucous membrane of the antrum (*vide* Case 3) and a more radical treatment will be indicated if a complete cure be desired. In 27 of the 48 patients referred to, this method of alveolar drainage and irrigation was, or had been, adopted and patiently persevered in for periods varying in different cases from five months to ten years. After careful inquiries it was ascertained that only five had been cured so that they could dispense with their tube, while the rest had to continue the drainage although all their original symptoms were greatly relieved. Hence we may gather that a small proportion of chronic cases will be cured by alveolar drainage, that a much larger proportion will only be relieved, and that as a general rule it will (with certain exceptions) be wise to let all patients have a trial by this method which is at once simple, involves practically no interruption of business, and will greatly relieve, even if it will not cure, all symptoms.

CASE 3. *Chronic antral empyema treated by radical operation.*—The patient, a female, aged 41 years, was seen in October, 1903. For many months she had had marked obstruction to breathing through the left nostril with constant "wearing" pain over the left frontal region. The discharge of pus from the nose was profuse and "soaked the pillow" at night. She had no energy and was always feeling unwell and depressed. Examination was made in an identical manner as for Case 2 and with similar results except that in this patient the left nasal cavity and posterior choana were filled with polypi bathed in pus. The tongue was furred, the complexion was very "muddy," and altogether the patient appeared to be in low health. The second bicuspid and both molar teeth were "dead." It was obviously useless to employ simple alveolar drainage in such circumstances and hence on Oct. 15th under chloroform anæsthesia I performed the following radical operation upon the left antrum. The "dead" teeth having been removed an incision was made over the canine fossa parallel to, and just below, the junction of the cheek and gum. The soft tissues were retracted and a large opening of the size of a sixpenny piece

was made in the canine fossa. The diseased polypoid antral mucous membrane bulged through the opening and foul pus escaped The sinus was now carefully and thoroughly curetted, the free hæmorrhage being checked by strips of sterilised gauze moistened with a solution of adrenalin chloride 1 in 1000
wall of the

polypi in the middle nasal meatus as well as the anterior half of the middle and inferior turbinals were also removed.
packed with a strip of gauze
the
were
an
in by a rigor three weeks later the patient made a perfect recovery and is now (March, 1904) absolutely free from all her old symptoms and without a trace of pus in the nasal cavities

The last case is typical of many long standing antral suppurations and its main features of interest are. (1) the large polypi blocking the left nasal cavity, a result of ethmoidal inflammation secondary to the antral suppuration, (2) the marked improvement in the general health since the purulent focus has been removed, and (3) the complete cure of the local morbid conditions brought about by the radical operation. It was obvious that mere drainage and irrigation of the antrum would not have sufficed to effect any permanent improvement in this patient's condition To the question, What considerations should guide us in advising a radical operation upon the maxillary antrum? we may answer—1 The appearances met with in the middle meatus of the nose If in a long standing case of suppuration polypi be found in the middle meatus then it may generally be assumed that similar chronic degenerative changes are present in the antrum which only radical measures will suffice to cure I am aware that certain exceptions to this statement might be made, but it is a good working rule nevertheless 2 When the circumstances of the patient demand a rapid and complete cure of the sinus suppuration

During the past three years I have had the opportunity of performing this radical operation more than 50 times and I consider it to be one of the most satisfactory which the surgeon is called on to perform The symptoms which it aims at relieving are very troublesome ones, the operation is, in my experience, practically free from any risk except that of the anæsthetic,
more than three or
lent, and there is
least degree from
patient In the T
Great Britain for December, 1903, I have published a series of 33 consecutive cases with 30 verified cures and the three exceptions in which an imperfect result was obtained were not operated upon by the method above described and there

70 and 71 years respectively, who themselves selected the radical measure and recovered without a bad symptom

Beyond a temporary neuralgia I have only experienced two complications: (1) a mild epiphora which passed off within three weeks and was apparently due to some swelling of the soft parts around the lower end of the lacrymal duct, and (2) a perforation in a high roofed hard palate arising *three days after the operation and gradually enlarging to* the size of a green pea This was easily closed

CASE 4 *Suppuration of the left frontal, ethmoidal, and maxillary sinuses*—The patient, a female, aged 33 years, was seen on March 3rd, 1903 She complained that for two years she had had a constant discharge of "offensive matter" from the left nostril and that the nose was obstructed on that side. She suffered from frequent headaches over the left eyebrow and there was a constant feeling of "oppression in the forehead" "Singing in the left ear" and temporary attacks of deafness were more recent symptoms. By the tests already enumerated in Cases 2 and 3 it was ascertained that the left antrum contained pus It was noticed, however, that even when the antrum had been washed free from pus and the middle meatus had been cleaned by wool mops, yet a purulent discharge quickly reappeared in this situation It was therefore necessary to determine whether it came from the ethmoidal or frontal sinuses or (what was more probable) from both Having again cleansed the middle meatus a small wool mop was forced upwards against the lower end of the frontal sinus to prevent any discharge flowing from it, but in spite of this pus gradually reappeared in the middle meatus, a fact which indicated probable suppuration in the anterior group of ethmoidal cells—i e, those situated below the attachment of the middle turbinal bone to the lateral ethmoidal mass Having again cleansed this region the aforementioned wool mop was removed and pus immediately appeared in the meatus and its flow was increased by passing a probe upwards towards the frontal sinus. In this way the diagnosis of combined empyemata was rendered practically certain

Operation was performed on March 27th The patient having been anæsthetised the left posterior naris was plugged with a sterilised sponge in order to prevent the flow of blood into the lower air passages during the operation upon the nasal sinuses By means of suitable nasal scissors and a cold wire snare the anterior halves of the middle and inferior turbinal bones were removed and the frontal sinus was opened through an incision in the inner half of the left eyebrow, the lower internal limit of the wound being situated a quarter of an inch above the internal palpebral ligament (Fig 1) Having turned back the soft parts and periosteum a small area of the anterior sinus wall was removed with chisel and mallet Pus was discharged through the aperture and through it bulged the diseased and swollen mucous membrane The anterior sinus wall was now completely removed by suitable bone forceps (Jansen's), the diseased mucosa were carefully but completely curetted away (Fig 2), the fronto nasal canal was enlarged by means of "burrs"[1] and the anterior ethmoidal cells were also broken down by means of the latter instruments, as well as by sharp ring curettes passed up from the nostril. The bony wound was lightly packed with gauze and a rubber drainage tube was passed into the naso frontal canal to preserve its patency until the sinus cavity had later filled with granulation tissue, when the tube was removed (fourth week) The radical operation was then carried out upon the corresponding antrum exactly as in Case 3 and its contents were similar
treatment of

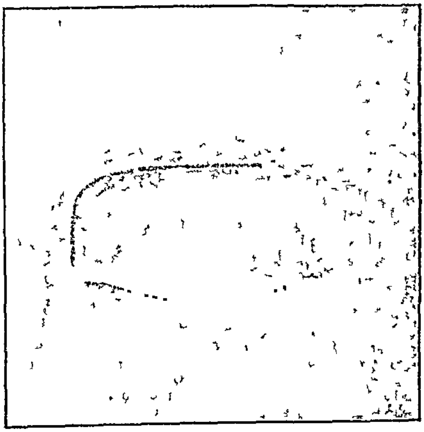
by granulatio
the rubber tube leading into the nose was also allowed to close

FIG 1



Curved line of incision for radical operation on frontal sinus

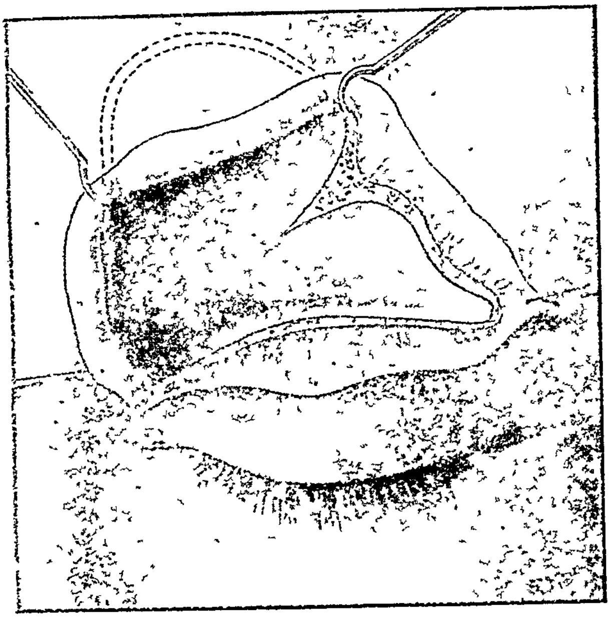
Treated in this way a frontal sinus of average size takes from four to five weeks to heal completely, but the patient can usually leave his bed on the third or fourth day after the operation The last patient (Case 4) was exhibited before the Laryngological Society of London at its meeting in March, 1904. She was perfectly cured of all her symptoms and the scar in the eyebrow was almost unnoticeable.

---

[1] Made for me by Messrs. Mayer and Meltzer

The above case is of interest in that it illustrates (1) a frequent combination of empyemata; (2) the addition of aural symptoms which disappeared when the nasal condition was remedied; and (3) the very small amount of scarring even when the sinus is totally obliterated. It may here be mentioned that the amount of disfigurement caused by the contraction of the scar of an obliterated sinus depends entirely on the depth (from before backwards) rather than on the superficial extent of the sinus.

FIG. 2.



To show cavity of sinus after complete removal of the anterior wall and of diseased mucous membrane. The dotted line indicates upward extension of the sinus, the anterior wall of which can be easily removed through the usual incision. The diagram also illustrates the incomplete (always) division of the sinus cavity by a bony septum.

CASE 5 *Chronic bilateral frontal, ethmoidal, sphenoidal, and maxillary sinus empyemata.*—The patient was a female, aged 41 years, who was seen on Oct. 15th, 1902 There was a history of fœtid purulent discharge from both nostrils for ten years, coming on immediately after an attack of enteric fever. She suffered from severe headaches with a "forcing pain" between the eyes and at the back of the head; these pains were always worse in the morning. She also suffered from occasional attacks of giddiness and a dull heavy feeling in the head which rendered her quite unfit for her work She was constantly tired and low-spirited. The examination conducted on the lines already indicated (Case 4) revealed the implication of all the sinuses in a chronic suppurative inflammation and it was obvious that only radical measures offered any hope of permanent relief. Operation was performed on Jan 9th, 1903 Both frontal sinuses were operated upon in identically the same manner as detailed in Case 4 In addition the whole lateral mass of the ethmoids and the anterior walls of the sphenoidal sinuses were removed as far as possible by means of ring curettes (Mayer's) passed up from the nostril and guided by means of the sense of touch aided by light reflected from a forehead mirror. On Feb 2nd both maxillary antra were operated upon as in Case 3 and the after-treatment was essentially the same as in Cases 3 and 4 The patient made a perfect recovery and was shown at the April (1903) meeting of the Laryngological Society of London to demonstrate (1) the very slight scarring after total obliteration of both frontal sinuses; (2) the complete absence of any pus in the nasal cavities; and (3) the curious pearly appearances presented by the posterior walls of the sphenoidal sinuses as seen through the large openings in their anterior walls.

CASE 6 *Bilateral chronic empyemata of the frontal, ethmoid, and maxillary sinuses also of the left sphenoidal sinus The maxillary sinuses were only acting as reservoirs of pus for the discharges from the other accessory cavities*—The patient was a man, aged 60 years, who was seen in October, 1901. He had suffered for seven months from severe neuralgia over the left forehead and a purulent, very foul discharge from both nostrils. He thought the latter dated from an influenzal attack two or three years previously. Examination, carried out as in Cases 3, 4, and 5, revealed conditions almost identical with that described in Case 5, except that in this patient the nasal septum was deflected so strongly to the left side that the higher regions of the nose could not be carefully examined. On Oct. 24th, 1901, alveolar drainage tubes were inserted in both maxillary antra as the patient declined any severer measures. For two years he had irrigated these sinuses with mild antiseptics twice daily and although he said that the discharge of pus was less yet he still used "50 handkerchiefs a week." On June 2nd, 1903, owing to increasing frontal headache and general ill-health, the patient consented to radical operations upon his frontal sinuses and assisted by Mr. C. J. Bond of Leicester I opened both sinuses and destroyed the ethmoidal cells in the manner already described in Case 4. Owing to the patient being very weak under the anæsthetic we were compelled to hurry over the left frontal sinus and I was unable thoroughly to clear the corresponding ethmoidal region so that a small suppurating fistula remained which we remedied by a further operation three months later.

The patient made an uninterrupted recovery from the first operation and it was decided to deal with both maxillary antra a fortnight after the frontal sinus operations. Curiously enough, however, from the day the higher sinuses were operated upon the discharge from the maxillary antra ceased. In other words, during five or six years they had been acting as reservoirs for the discharges from the higher sinuses without being generators of pus. In this respect the antra may be compared with a urinary bladder from which pus ceases to be discharged when the source of the latter—e.g., a calculous pyelitis—has been removed.

Since the above I have operated on three similar cases and such experiences emphasise the advisability in cases of combined empyemata of always dealing first with the higher sinuses rather than proceeding in the reverse direction, as advised by Moure of Bordeaux. It is not a little curious that I have recently examined the nephew of the patient (Case 6) whose sinuses are all similarly affected.

CASE 7. *Combined empyemata of all the nasal accessory cavities, chronic bilateral suppurative otorrhœa, enlarged tonsils, and adenoids.*—The patient, a female, aged 25 years, was first seen in June, 1901. A history of long-continued, very profuse purulent secretion from both nasal cavities, general ill-health, anæmia, lassitude, and depression was given. This was, indeed, a pitiable case, for I did not know where to commence and indeed the risk of operating at all with such septic conditions could not be ignored. After many delays I removed an aural polypus from the right ear together with a carious malleus and incus; also at the same operation the tonsils and adenoids were removed and alveolar drainage tubes were inserted in both maxillary antra. The patient quickly recovered and as a result of antiseptic and cleansing remedies the aural discharge ceased in about five weeks and has never given trouble since. From time to time numerous polypi were removed from the nose but the secretion of pus continued to be very profuse and the patient desired any operation which might hold out reasonable prospects of relief. That it was not a case to venture upon lightly was made patent to me by the fact that when a cannula was passed into the right frontal sinus the injected fluid returned by way of the left nostril, indicating a perforation in the sinus septum. Then again the same cannula could be passed a long way up into the sinus, indicating that that cavity was an extensive one. Consequently on many occasions I tried the injection of antiseptic lotions of varying composition, including iodoform emulsion, but all to no purpose—the discharge continued as freely as when nothing was done.

On Feb. 21st, 1903, I opened both frontal sinuses by the methods already indicated (Cases 4 5, and 6) The cavities were the largest I had ever seen and extended not only to the temporal regions but upwards for two and a half inches from the root of the nose. They were filled with chronic polypoid degenerated mucous membrane, inclosing several loculated collections of fœtid pus. The sinuses were thoroughly curetted and lightly packed and some idea of their extent may be imagined if it be borne in mind that 23 feet 4 inches of ribbon gauze, two inches in width, were inserted as a first dressing. After a long and tedious convalescence the external wounds healed and considering the enormous size of the cavities the depression is very slight, and that mainly over the left sinus. Unfortunately, time did not allow of my dealing with the sphenoidal or with all the ethmoidal cells and these still secrete some pus. I trust that some day the patient will allow me to try to make a more perfect result for her.

The chief points of interest in this remarkable case are: (1) the extensive involvement of all the sinuses; (2) the infection of the tympana which occurred 18 months after the nasal symptoms were established; (3) the destruction of the septum dividing the frontal sinuses; and (4) the large size of the frontal sinuses and the curious apparent isolation of many of the abscesses contained in the diseased mucous membrane. Undoubtedly these communicated with the nasal cavity through the fronto-nasal canal or through the ethmoidal cells.

CASE 8. *Bilateral chronic empyemata of the frontal, ethmoidal, and antral sinuses.*—The patient, aged 44 years, was seen on April 4th, 1903. He gave a history of bilateral nasal suppuration and formation of polypi of 24 years' duration. All the symptoms were aggravated by an attack of influenza four years previously. Both frontal sinuses and maxillary antra were dealt with by radical operations, an interval of a fortnight elapsing between the operations on the higher and lower cavities.

The patient made an excellent recovery but the latter was not attained without anxiety on my part because the posterior wall of the left frontal sinus underwent a superficial molecular necrosis. It first became of a dirty greenish-grey colour, then small spicules of bone separated with the dressings, but no complete perforation of the bony wall could ever be observed. Healthy granulations gradually sprang up and eventually the sinus was completely obliterated.

CASE 9. *Empyema of the left antral, ethmoidal, and sphenoidal sinuses complicated by chronic suppuration in the left lacrymal sac.*—The patient was a man, aged 60 years, who was seen in consultation on Sept. 25th, 1902. A history of chronic purulent, offensive discharge from the left nostril of ten years' duration was given. There was some more or less constant pain in a spot which corresponded with the junction of the infra-orbital margin with the ascending process of the maxillary bone. No pus exuded from the lacrymal sac on pressure although the latter caused pain. Ten years previously an alveolar drainage-tube had been inserted into the left antrum and irrigation was carried out for eight years. Two years ago the antrum was curetted on two occasions through a large opening made in the alveolus but there could still (Sept. 25th, 1902) be seen in it a quantity of fungating granulation tissue bathed in very foul-smelling pus. Owing to a marked deflection of the septum to the left in addition to a prominent "septal spur" on this side it was difficult to examine the left middle meatus, but as far as this could be done with Killian's long-bladed nasal speculum the frontal sinus seemed free from disease.

On Sept. 19th, 1903, under chloroform, the radical operation upon the left antrum was performed (*vide* Case 3) and the spur was removed from the septum. As a result of the operation it may be stated: 1. The discharge of pus greatly diminished but a small quantity could always be seen high up in the posterior ethmoidal region and it was very foul. 2. Probably some of this was forced during convalescence into the right antrum because ten days after the radical operation the patient exhibited symptoms of pus in the right antrum. These were speedily relieved by alveolar drainage and irrigation. 3. The pain below the lacrymal sac was *not* cured and during some bouts of it the left eye watered freely. 4. Further examination during convalescence showed that a small quantity of foul pus escaped from the sphenoidal sinus. I washed out this cavity many times with various antiseptics, including 4 per cent. formalin, but irrigation had little appreciable effect in reducing the amount of secretion. It was now decided that, as the amount of pus from the ethmoidal and sphenoidal cavities was so small compared with the amount secreted before the radical antral operation, that it would be advisable for the patient to go to his old home (near Vienna) for a few weeks' change and if the pain in the cheek and slight discharge did not cease that when he returned to London the question of opening up the sphenoidal and posterior ethmoidal cells should be considered. During his holiday an acute exacerbation of the inflammation in the lacrymal sac occurred and Dr. Müller (Vienna) was consulted, while Professor Hajek examined his nasal cavities. Under local anæsthesia the lacrymal sac was removed and showed evidence of long-continued irritation and inflammation. After this operation the pain already referred to disappeared and the secretion of pus quickly diminished. In December last Professor Hajek, Dr. Müller, and I met in London to discuss the advisability of further operative treatment on the accessory nasal sinuses, but as the patient's condition was so vastly improved we unanimously consented to wait a little longer. The result has been entirely good in that when last seen by me (in February, 1904) he was perfectly well in all respects and without a trace of any pus in the nose.

It is obvious that my radical operation on the antrum, while completely ridding this sinus of its share in the secretion of pus and greatly diminishing the quantity of the latter, did not get entirely to the root of the matter and I must confess to not having suspected the lacrymal sac of any coöperation in the symptoms. The sphenoidal sinus was obviously infected by the septic secretion from the lacrymal sac which seems to have passed backwards through the posterior ethmoidal cells to the spheno-ethmoidal recess, from which direction it could often be seen issuing. It is of practical interest to notice how quickly the sphenoidal sinus suppuration ceased when once the source of infection was removed and such observations should encourage us not to be too ready with active intervention until we have exhausted simpler modes of treatment and given a fair chance to the natural recuperative powers of the diseased sinuses.

GENERAL CONSIDERATIONS.

A brief study of the foregoing cases will illustrate some of the etiological factors in inflammation of the nasal accessory sinuses. For many years it has been recognised that the primary infection may arise from local or more general causes. With regard to the former, septic inflammation around the roots of dead bicuspid and molar teeth forms a very frequent cause of antral suppuration and from this situation the disease may gradually extend into the ethmoidal and frontal sinuses. In the 52 cases from which the above-recorded ones are selected, dead or carious teeth were present in each one and upon the side of the diseased sinus; no doubt in some cases this was a coincidence because only small degrees of caries were present but in a large number the dental trouble seems undoubtedly to have been the cause of the sinus suppuration. Amongst other local causes of sinus empyema may be mentioned the septic discharges arising from unhealthy conditions of the post-nasal and nasal chambers—e.g., suppurating lacunæ of old adenoid growths and decomposing secretion in certain well-marked forms of hypertrophic rhinitis. At the present moment of writing I have under treatment a case of suppuration in the sphenoidal sinus the result of tertiary syphilitic necrosis of its anterior wall.

With respect to the general etiological factors it is a well-established fact that many cases of suppuration date from an attack of one of the specific fevers and of these influenza has played a very prominent part during recent years. Case 5 is interesting in that it undoubtedly arose after a severe attack of typhoid fever.

In connexion with the chronic suppurative lesions with which we are now concerned two important questions demand an answer—viz., What is the risk to life: (1) if the disease be left to take its course? and (2) if operative procedures of a radical nature be undertaken for its relief?

1. With regard to the first question, the risk to life will depend upon the situation of the sinus relative to neighbouring structures of vital importance. In the case of the antrum, aside from the evil influence upon the general health induced by constantly swallowing septic matter, there can, practically speaking, be no danger to life. With empyemata of the frontal, ethmoidal, and sphenoidal sinuses the case is very different and many cases terminating in fatal meningitis have been recorded. So long as the drainage from the sinuses remains free the patient will only suffer from the results of the absorption of septic matter into the general system and the annoyances caused by the nasal discharge, but at any time a severe cold in the head or the increase in size of polypi or other inflammatory swellings may produce a retention of septic products within the sinus and evil possibilities may at once present themselves.

2. The risk to life when operative treatment is undertaken will in the main depend on two factors: (1) the sinus

involved; and (2) the surgeon's familiarity not only with the region in which he is working but also with the many technical details of intranasal manipulation and operation. The maxillary antrum may be operated upon and subjected to very considerable traumatism without any appreciable risk because it is far removed from any vital structures. Quite the reverse holds in the case of the higher sinuses and many fatal results have occurred as a direct result of operative interference. These "regrettable occurrences" have generally followed radical procedures upon the fronto ethmoidal sinuses and in nearly all the cases which I have been able to investigate (including two of my own) the cause of failure may be summed up in two words—viz., deficient drainage.

After having given a fair trial to the many methods which have been advocated for the treatment of chronic empyema of the fronto-ethmoidal sinuses, I am in entire accord with those who maintain that only complete obliteration or destruction of the bony cavities offers any prospect of a permanent radical cure. In the case of the frontal sinus the anterior bony wall should be entirely removed and any recesses of the sinus thrown into the main cavity by the breaking down of partition walls. Especially will this be necessary in those instances where certain suppurating ethmoidal cells extend outwards immediately below the floor of the frontal sinus and are only separated from it by a thin, almost transparent septum of bone. Furthermore, the fronto-nasal canal must be enlarged and suppurating anterior ethmoid cells in its immediate neighbourhood must be carefully broken down or reinfection of the higher sinus will occur. Having proceeded thus far the latter cavity should be lightly packed with sterilised gauze which can be changed on alternate days until the obliteration of the sinus by granulation tissue is complete. From the moment the operation is completed the motto of the surgeon must be, "Free, unhindered, spontaneous drainage," and if he secures this he need never fear that any serious harm will come to his patient.

The treatment of ethmoidal and sphenoidal suppurations will demand from the surgeon a practical familiarity with intranasal operations and technique and without having acquired these he and his patient will probably be disappointed with the result of surgical intervention. Generally speaking, operative manipulations in the ethmoidal region will be safe when they are carried out below the level of insertion of the middle turbinal bone and much excellent information may be gained as to the progress one is making by the frequent examination of the diseased area with the tip of the little finger passed upwards through the nostril. In this way the limit between soft chronically inflamed (rarefying osteitis) and firm healthy bone can often be ascertained. In most operations upon the ethmoidal (and frontal) sinuses it will be a great advantage to remove at least the anterior half of the middle turbinal bone as a preliminary procedure not only because it is often itself chronically inflamed but the absence of this structure will enable the surgeon to deal more easily with the lateral mass of cells and free drainage will be secured during the after-treatment. A dangerous area is reached when instruments are used above the level already mentioned, for here we are in close proximity to the cribriform plate.

The sphenoidal sinus is best reached through the nasal cavity and it will nearly always be necessary first to remove the middle turbinal bone. In dealing with this deep seated sinus the surgeon must make use of a bright reflected light and thoroughly define the anterior sinus wall and its ostium before he commences removal of the same. Operations upon this sinus and the posterior ethmoidal cells are best carried out under the influence of cocaine (20 per cent.) anæsthesia, and the most suitable instruments for breaking down the thin bony structures in these regions are Hajek's series of hooks. The inside of the sphenoidal sinus should never be curetted, for if a large opening be made in the anterior wall suppuration will generally cease if the cavity be frequently cleansed with mild antiseptic lotions. Curettage of the inside of the sinus, and especially of its upper and outer walls, may prove to be a very dangerous procedure. Those who have had much experience in operating upon the sinus will agree that it is much easier of approach than would [illegible] seem probable. The opening in its anterior [illegible]s be made as large as possible, for it [illegible]ked tendency to contract. [illegible]eded it must, I think, be conceded that [illegible]n the surgical treatment of the sup[illegible]e nasal accessory sinuses. On the contrary, only in so far as the surgeon bases his treatment on the fundamental principles of surgery can he look for a successful result of his intervention. In one sense only can the subject be regarded as "specialised" and that is in the matter of the technique which is rendered necessary by the peculiar anatomical and physiological characteristics of the regions themselves. For these reasons a variety of special instruments and methods of examination are absolutely essential. If, however, the surgeon can spare sufficient time for perfecting himself in the manipulations necessary for the investigation of the diseases of the nasal accessory sinuses the resulting advantages should be threefold—viz., to the surgeon himself will be opened up a subject of fascinating interest and of great possibilities, to the patient will the prospect of relief from suffering be enhanced, while surgery will continue in no small degree the advancement of its science and art.

NOTE ON THE VALUE OF HOT-WATER INJECTIONS AS A SUBSTITUTE FOR NUTRIENT ENEMATA IN THE TREATMENT OF GASTRIC ULCER.

BY W. PASTEUR, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL AND CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

FOR the last 18 months I have treated all cases of gastric ulcer requiring rectal feeding by enemata of plain water at the temperature of the body with results sufficiently uniform and satisfactory to be worth recording. I do not propose to discuss the indications for rectal feeding but rather to compare the results obtained when plain water is used instead of beef-tea, milk, eggs, starch, and the many other foodstuffs which are employed in concocting the four- or six-ounce enema which has become consecrated by usage in the treatment of these cases.

It is generally held that the rectum is capable of absorbing well (1) peptone; (2) white of egg, especially with salt added; (3) raw beef juice; and (4) starch and sugar and, to a far less extent, milk proteids and gelatin. It is also common knowledge that patients can be kept alive by this method of alimentation in comparative comfort for several weeks. But the comfort is only comparative. Relief from gastric pain and vomiting is usually prompt, but very soon other symptoms, attributable mainly to the rectal feeding, make their appearance. Of these the first to arise and the most important is thirst. Nor is this surprising seeing that the total amount of fluid given per rectum in the 24 hours varies from 16 to 40 ounces at the outside. It is usual to relieve thirst by allowing the patient to sip a small quantity of hot water from time to time, or to suck ice, or from half a pint to a pint of warm water is injected into the rectum once or twice in the 24 hours. This last method is the best but it has the drawback of increasing the total number of enemata and thereby the risk of rectal intolerance.

Ice by the mouth should, in my opinion, always be avoided. It often fails to quench the thirst and it is difficult to limit the amount taken. I have long since given up the use of ice in the treatment of gastric ulcer except in an ice-bag over the epigastrium, suspended from a cradle so as to insure the lightest possible contact, for the relief of pain. Sipping hot water undoubtedly relieves thirst in some cases, but as the primary object in the treatment of this condition is, so far as possible, to secure physiological rest for the stomach, I think this is best achieved by giving nothing whatever by the mouth for the first few days, at all events, and this can only be done by administering a sufficient quantity of water per rectum to prevent thirst from becoming urgent.

Another symptom which occurs in the course of a few days, I believe in all cases where the enemata contain beef-tea, is an unpleasant taste of beef-tea in the mouth not infrequently associated with a feeling of nausea. This symptom is sometimes very distressing.

By substituting ten-ounce enemata of plain water at a temperature of 100° F. for the smaller nutrient enema at present in general use it is possible to prevent thirst altogether in the great majority of cases and to do away entirely with the unpleasant taste in the mouth.

I am informed by my ward sister, to whose careful observations I am largely indebted, that since we have adopted the plain-water enemata the patients have been altogether more comfortable and much easier to manage than under the old *régime* of small nutrient enemata. I am quite satisfied that the general condition of the patients is at least as good, if not better, and that recovery takes place as quickly, and I may add that since I first adopted this treatment in November, 1902, I have not once had occasion to order a nutrient enema and have not once met with an untoward symptom in any of my cases.

It is a good plan to begin with a five- or six-ounce enema, increasing the bulk each time by one ounce until ten ounces are easily retained. I have not found it necessary to go beyond this. The enemata are given every four or six hours [illegible]. In most cases it is possible to [illegible] by giving small quantities of [illegible] mouth before the end of a week but in several instances my patients have had nothing whatever by the mouth for ten days or a fortnight, and in one or two cases for nearly three weeks, without making any complaint or giving any indication that they were any the worse for their prolonged abstinence. To sum up, the method here advocated gives results at least as good as the ordinary nutrient enemata. It is far simpler to carry out, it is decidedly more bearable for the patient, and incidentally it does away with the unpleasant and offensive daily wash out.

The results obtained with enemata of plain water suggest some interesting reflections on the value of the foodstuffs of [illegible] the absorptive power of the [illegible] to discuss these points.

[illegible]

ANKYLOSTOMIASIS.[1]

BY J. OHRONNELL, M.R.C.S. ENG., L.R.C.P. IREL.,
MEDICAL OFFICER OF HEALTH, HINDLEY URBAN DISTRICT COUNCIL; PRESIDENT OF THE WIGAN MEDICAL SOCIETY.

THE subject of my paper is, it seems to me, one that must peculiarly appeal to a medical society situated in a colliery district. The disease ankylostomiasis is one that the majority of the members can know little of and that only from reading. I find in Taylor's "Medicine," sixth edition, 1901, that the disease is unknown in England and in the second edition of Quain's "Dictionary of Medicine" the same appears, so we err in good company. My own attention was first drawn to the matter about 12 months ago in connexion with the appearance of the disease in Cornwall and since then I have taken a deep interest in the subject and have done all I could to interest others. I take it we may at any time have to deal with the pest and those of us with colliery sick clubs will have to give freely their time and labour in curing the victims of the ailment. It is difficult to cure and the ankylostomum duodenale once introduced into a colliery is very difficult to destroy. In England the Government, the colliery proprietor, and the collier through his union have seriously taken up the subject. The *Colliery Guardian* sent a commissioner (Mr. Salter) to study the disease in Westphalia and his report is issued as a supplement and a second edition appeared about a month ago revised by Dr. Haldane. The latter was sent to Westphalia and Cornwall by the Home Office and his reports have been issued as blue-books. About three weeks ago the Home Office issued a memorandum on the mode of detection of the ovum of ankylostomum duodenale.

You will notice the first paragraph begins: "It is considered by Dr. Haldane not improbable that worm disease already exists in other mines in Great Britain besides those which are infected in Cornwall." My own opinion, and I advance it in all humility, is that we have had it in our own district, if not present now, but that fortunately for us the ovum did not find a suitable nidus—viz., air, moisture, and a temperature over 60° F. We have collieries here in which we could find some, if not all, of these requirements.

The ankylostomum is a nematode worm, the male being one-third of an inch long and the female about half an inch long; it infests the jejunum and not the duodenum. The female lays an enormous number of eggs which can only become larvæ after their discharge in the fæces. Then, with a high temperature, absence of sunlight, presence of oxygen, and moisture, the eggs hatch in a week, producing free larvæ. Experimentally it has been proved that ova and free unripe larvæ are, when swallowed, unable to develop into adult worms. In a matured stage they become productive on entering the small intestine. Antiseptics so far are of very little use. Deprived of oxygen or exposed to sunlight they die. In ordinary water they live for long periods but drying kills them at once. Dr. Stockman says they live for about six years. The human intestine is its only known host.

The symptoms of the disease are those of anæmia in a serious form: pallor, palpitation, dizziness, dyspnœa on exertion, loss of appetite, and sometimes diarrhœa or melæna. In Cornwall an irritable pustular skin eruption, locally known as "bunches," has been found. Though not often fatal it will be easily understood why the afflicted are incapable of work. I ought to mention here that a great number of men have been found to be infested with the worm and yet show no symptoms of anæmia—a fact that tends to confirm my own impression that men returning from service in India, Egypt, and South Africa must have brought the worm here. It is recognised that these men constitute an almost equal danger with the others. Until very recently we were led to believe the pallor of the body was due to hæmorrhage and the worms sucking the blood from the intestine. Dr. Haldane and Dr. Boycott, in the *Journal of Hygiene*, prove that it is not so. Measurements made by them show the anæmia to be due to a great increase in the total volume of the blood with a corresponding dilution of the hæmoglobin and in consequence the fainting, dizziness, and palpitation are caused by the defective aeration of the tissues, and the heart in particular, the condition being analogous to that of poisoning by carbon monoxide.

I need not go into the treatment, which in England has been thymol and in Germany male fern, though a number of other drugs have been tried. What we ought to do is to try to improve the sanitary conditions of our collieries. You all know that underground, with a very few exceptions, nothing is done. A collier is free to go where he likes. He fouls his hands and eats his food at his work and indeed often enough at home he will not wash them before taking his dinner. No one asks that he shall have a lavatory in his working place but he ought to have suitable pails placed at convenient points in and about the workings. The pails should be brought to the surface daily and their contents burned in the furnace, run into a cesspool, or spread on the land. A great number of closets, water-closets where possible, must be provided on the surface and possibly some day there may be a bath on the surface. In Germany every collier has to have a bath at the colliery and to change his working clothes for others before he is allowed to leave the works. Lastly, I contend that every colliery ought to have a supply of pure fresh water not only on the bank but in the pit. How many times have you seen wounds that have been washed with tea because no other fluid was to be had.

Hindley.

TRANSPLANTATION OF TENDON FOR MUSCULO-SPIRAL PARALYSIS.

BY H. M. W. GRAY, M.B., C.M. ABERD., F.R.C.S. EDIN.,
SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

THE following case presents some remarkable and interesting facts.

A boy, aged 16 years, fractured his right humerus and by a fall during convalescence the fracture was made compound. Thereafter the musculo-spiral nerve became included in the callus. To free this, operation was performed and apparently, judging from the resulting paralysis, the nerve must have been severed during the manipulations. Further operations were done to improve matters but without success. Two years after the last operation the boy came under my care. At that time musculo spiral paralysis was complete. He could not extend the fingers or thumb at the metacarpo-phalangeal joints in the very slightest degree, although, as usual, the terminal phalanges could be extended by the action of the interossei and lumbricales. The fingers were fully flexed on the palm and the wrist was also flexed. He could not supinate in the least when pronation was complete but if the forearm and hand were placed midway between pronation and supination, supination could be carried slowly and feebly to almost the full extent (by the biceps). The flexors and pronators were all normal.

---

[1] Presidential address read before the Wigan Medical Society on April 14th, 1904.

I exposed the tendon of the flexor carpi ulnaris by a longitudinal incision over it, cut it across just above the pisiform bone, and detached a few of the lowest fibres of the muscular attachment to the ulna. I made then an oblique incision over the back of the forearm, reaching downwards as far as the level of the wrist-joint, and separated out the common extensor tendons. A tunnel close to the ulna was made through the interosseous membrane, just above the upper border of the pronator quadratus, a forceps was passed through this from back to front, and the tendon of the flexor carpi ulnaris was pulled through. Hyperextension of the fingers and wrist was made, the extensor tendons were cut across just above the level of the wrist-joint, and the distal parts were sutured to the end of the flexor carpi ulnaris tendon. The wounds were closed and the elbow-joint, forearm, and hand were enveloped in dressings and plaster-of-Paris, the wrist and fingers being fixed in the hyperextended position and the elbow flexed.

I expected that the boy would have to be educated to attempt to make ulnar flexion at the wrist when he wished to carry out extension of the fingers. At the end of three weeks after the operation, when the dressings were removed, the wounds were soundly healed. I flexed the fingers cautiously and then asked the boy to straighten them. To my surprise he did so at once and to the full extent. I leave physiologists to explain *why* a flexor nerve and muscle should, in the circumstances, respond so quickly to extensor impulses. The boy told me that he had tried to move the fingers under the plaster but I had not indicated to him how the movement of extension was to be produced. This was all the result I expected, but I found that the boy could now supinate, even though the forearm was previously fully pronated, and that supination was more complete than before. These movements are now carried out easily and strongly. The boy is so pleased with the result that he does not think it necessary to submit to further operation to give him extension of the thumb. When at rest the thumb lies more or less flexed in the palm. When the boy attempts to extend it it is abducted from the palm, the metacarpal is drawn inwards, and the terminal phalanx is slightly extended, probably from increased tension of its extensor tendon. All this permits the boy to grasp certain objects of narrow calibre without having to place the object in position with the other hand. When he attempts extension of the thumb one can see the tendon of the flexor carpi radialis becoming prominent. This indicated that it could be used to produce extension of the thumb in a way similar to that carried out with the ulnar flexor. What I now wish is to transplant the tendon of the flexor carpi radialis through the interosseous space close to the radius, and then attach to it the severed tendons of the extensors of the thumb at different levels so that extension of the proximal phalanx will be obtained slightly in advance of extension of the distal one It may be some time before the boy submits to this procedure, so I think it right to record the case now. I have not heard of any similar operation being done for musculo-spiral paralysis.

Judging from the great success which has attended the transplantation of the flexor carpi ulnaris I have not the slightest doubt that transplantation of the flexor carpi radialis on to the thumb extensors will give equally good results. The latter procedure will increase still further the power of supination. I recommend that both should be transplanted at the same sitting. There is no necessity to transplant the pronator teres in order to procure supination (as Tubby has done). This operation diminishes largely the power of pronation. In the operation I recommend two comparatively useless muscles are made to fulfil very useful functions and I feel certain that approximately normal movements will be the final result. Of course, such an operation is superfluous where successful nerve suture can be done.

Aberdeen.

THE RESULTS OF TREATMENT IN 301 CASES OF PHTHISIS BY OPEN-AIR METHODS.

BY DAVID LAWSON, M.A. ST. AND., M.D. EDIN.,
SENIOR PHYSICIAN OF THE SANATORIUM, BANCHORY, SCOTLAND.

IT is not without considerable feelings of misgiving on the part of the writer that he has yielded to the pressure which has been brought to bear upon him from various quarters to publish the results of the experience gained during the past three years of sanatorial treatment of phthisis at Banchory, for, as is well known, there exists in the minds of no inconsiderable section of the medical profession, not without fair reason, a well-marked prejudice against statistics of so-called "cures" and the more so when, as in the present instance, the statistics furnished emanate from the not altogether disinterested source of a paying institution. In another quarter he has expressed sympathy with that prejudice in the following terms: "It is therefore plain that if we are to be guided by the evidence furnished by statistics as to the value of the sanatorial treatment in phthisis then we must be prepared to ignore in our calculations those which reach us from paying sanatoria."[1] This statement was made in course of a criticism which was written after having made a careful study of the results published during the previous year by various classes of sanatoriums at home and abroad, for in these this remarkable fact was brought out, that whilst the percentage of cures in the pauper sanatoriums sometimes fell so low as 2 per cent., and in no case exceeded 15 per cent., those claimed by paying institutions invariably amounted to from 50 per cent. to 80 per cent.—in one case to as high as 100 per cent. And yet, notwithstanding these facts, it has appeared to him that, in view of the already large and steadily increasing number both of the profession and of the public whose interest in the subject is undoubted and who are anxiously awaiting the results of the treatment carried out in our own land before they definitely decide to accept or to reject the claim which has been made on behalf of sanatoriums as curative agents in cases of tuberculous diseases, it is his duty to place upon record the results obtained in those specially favourable conditions under which he has been working in the Scottish highlands during the past four years.

Whilst the weight of opinion may incline to the view that for a working basis we ought to found our calculations as to the efficacy of the treatment upon the results obtained in charitable or pauper institutions rather than upon those of wealthier sanatoriums, there is much to be said on behalf of those who hold the opposite view and contend that the results obtained at higher-class institutions furnish the better guide of the two. In considering the matter it is well to remember that sanatoriums for the pauper classes at present in existence in this country consist for the most part of modified mansion houses, located in the vicinity of large towns, run on lines of strictest economy, upon the medical and nursing side wofully understaffed, and sadly deficient in those scientific adjuncts to the treatment which wealth alone can supply. Moreover, the call upon their accommodation is so great that in order to relieve, if even in a small measure, the largest possible number of sufferers they are unable to retain their patients for a sufficiently long time to effect their cure. Indeed, many place three months as the limit of each patient's stay, after which, whether benefited or not, he must vacate his bed in order to make room for another. Contrast with this the case of a better-class institution the site of which in the first instance has been made the subject of careful thought and judicious choice, planned and built altogether irrespective of expense from the very commencement for the special purpose of carrying out open-air methods of treatment, with first-class laboratory and electrical installation, and relatively large medical and nursing staff resident in the building. And add to that the important consideration that its patients are largely drawn from the moneyed classes who come prepared to stay indefinitely so long as there exists the slightest chance of ultimate recovery being attained. It is surely reasonable to expect that in the latter circumstances the percentage of favourable results obtained shall far exceed that secured under the former conditions and as such shall supply a more accurate indication of the possibilities for good of the *régime* in question than can possibly be obtained in the case of the former. It is upon this ground, it is thought, that the facts here published merit careful consideration.

---

[1] Edinburgh Medical Journal, September, 1903.

The sanatorium at Banchory was opened in December, 1900, and at once received 20 patients, most of whom had been located in the neighbouring district awaiting admission. Between that time and December, 1903, there were treated and discharged 301 patients in all stages of the disease. No attempt was made to effect a selection of suitable cases. As was the experience in other pioneer institutions in this country, a large proportion of patients altogether unsuitable at first presented themselves for treatment, a fact which goes far to explain the heavy mortality that took place amongst the patients of the first year when compared with those of the two following years.

1. *Deaths.*—Dealing first with the mortalities which have taken place we find that out of a total of 302 patients which have passed through the sanatorium in the period under review 84 of these, equivalent to 28 per cent. of the whole, have died. Of that number 12 have died in the sanatorium itself, mostly, however, in the first year. No death has taken place from phthisis in the institution since October, 1902. One patient died in 1903, but in that instance the death was due not to phthisis but to the bursting of an aortic aneurysm. The fact that 62 out of 84, equivalent to 77·5 per cent. of the whole number of deaths, took place in patients who were admitted during the first year furnishes its own evidence as to the undesirably large proportion of unpromising cases with which one was at first supplied. Happily with a growing appreciation upon the part of members of the medical profession, as a whole, of the limitations of the treatment and of the desirability of advising its adoption at the earliest stage of the disease, the clinical type of case sent in later has steadily improved, until now in the vast majority of instances patients arrive at a time when there is every reasonable hope of their deriving permanent benefit from their stay. It is, therefore, a matter of probability, almost amounting to certainty, that future figures will prove much more encouraging than those which fall to be recorded here. Whilst the figures given represent all deaths which took place within that period, it is well to point out that in the cases of six patients, all subjects of phthisis, the immediate cause of death was due not to tuberculosis but to accidental complications. These were accounted for respectively by: (1) diabetic coma; (2) aortic disease; (3) aortic aneurysm; (4) appendicitis; (5) locomotor ataxia (rectal crisis); and (6) actinomycosis.

2. *Worse or no improvement.*—A large number of those who did not improve or who are now known to be worse are to be found in the class which has preceded this. But of those surviving one is aware of eight who derived, so far as could be judged, no benefit whatever from sanatorium treatment and whose condition is now worse than it was when they first entered the sanatorium.

3. *Improved, but disease not arrested.*—The vast majority of those who have improved have eventually had the disease arrested and so will come under consideration later, but there remains a certain number (13) who, whilst they have improved, still show signs of active disease. These for the most part have gone abroad, hoping to find in the reputed curative properties of foreign climate that factor which will ultimately promote their complete restoration to health. Some, however, have remained in Britain, and, so far as one has been able to learn through correspondence, the progress which the latter are making in no way seems to suffer by comparison with that which others are making in foreign lands. In regard to these cases one's experience abundantly substantiates that of Burton-Fanning[2]: "In no single instance has the course of the disease been materially different after going away than it would presumably have been had the patient remained in his own country."

We pass now to consider the more cheerful aspect of our subject—namely, those cases in which arrest of the disease has taken place. It is convenient to divide these into two classes—namely, (1) those in whom the disease has been arrested and the patient is able to work; and (2) those in which arrest is present but the patient is passing the life under conditions which admit of care being continued to be exercised. In 64 cases, in addition to signs of arrest in the chest, the patient's sputum if present failed to reveal the presence of tubercle bacilli either under the microscope or on inoculation before the patient left the sanatorium, or alternatively the sputum had entirely disappeared. There is a certain number of other instances in which the patients appear to be perfectly well and to be able alike to enjoy the burdens and luxuries of life, yet who occasionally produce a little sputum which on examination reveals the presence of tubercle bacilli.

It has been urged by some whose actual experience of open-air work is limited that the results obtained at sanatoriums in this country are usually unsatisfactory in so far as they are transient and that the patient rarely recovers his health sufficiently to be able to resume his old vocation in life. Indeed, there are many who go so far as to assert that in no circumstances should the patient again return to those conditions under which the disease was contracted. The fact that 111 (or 36·7 per cent.) of those treated during the past three years have now returned to, and are carrying on, their ordinary vocations in nearly every instance in this country is one which goes far to discount the value of that contention. No doubt in many instances the occupations followed are such as conveniently provide the patients with opportunities for continuing to live the life which they learned to live when undergoing sanatorium *régime*. Still there remains a very large number of cases in which, as in the case of lawyers, medical men, and merchants, the continuing of such life is attended with almost insuperable difficulties.

Duration of treatment.—The average term of residence in the sanatorium of these cases has been approximately five months. But it should be explained that here, also, the figures have suffered material modification by the inclusion of those taken from the first year's work. A comparatively large number of patients at first came in order "to learn the treatment" with a view to carry it on in country surroundings elsewhere. The term of residence in many of these cases did not exceed one month. During the past year such cases have rarely appeared, patients now for the most part preferring to remain until they are discharged. The longest period spent by one patient has been 22 months and the average of those discharged in 1903 was seven and a half months.

Weight gained.—The average weight gained has amounted to 16½ pounds. One's belief is that too much has been made in some quarters of mere gain in weight. The patients before leaving have for the most part been required to take considerable exercise, which has usually resulted in the weight being materially reduced below the highest point attained. In view of the fact, clearly demonstrated over and over again, that mere weight without condition is a dubious blessing, the desirability of making fit after signs of active disease have disappeared even at the expense of weight has, to my mind at all events, been conclusively established.

Residence abroad.—Those who have gone abroad fall under two groups. The first comprises a number who having completely recovered their health in this country afterwards went abroad in order to assume posts which their friends had procured for them. These have not gone abroad for purposes of treatment. Nevertheless, persuaded of the signal benefits which the colonies afford, they have gone there with the intention of spending the rest of their lives in the new country, as it appears to hold out to them the combined advantages of good business prospects and a fair chance of long life. The second is composed of quite another type. It is for the most part comprised of cases of old-standing disease, cases in which the disease has at length become to all appearance quiescent, but only after having caused extensive changes in the lungs. These cases find the rigors of winter climate somewhat trying at home and therefore go to sunnier climes where the conditions of life are pleasanter during the winter and early spring months than they are at home. Some, indeed, have settled abroad altogether for this reason. Such patients do not aim at ever [illegible]

Of those others who are living under careful conditions in our own country many are constrained to do so out of considerations of expense; but some prefer the society of their friends at home to the vaunted climatic advantages which expatriation affords and therefore remain at home from choice. But in every case recorded here there is sound evidence that the disease is in a state of arrest.

---

[2] THE LANCET, August 15th, 1903, p. 455.

Heredity.—A point of more than passing interest to statisticians brought out by these figures is the fact that of those who have recovered 98, or 51 per cent., have apparently no hereditary taint, whilst 94, or 48·9 per cent., possess a distinct hereditary burden.

GENERAL LESSONS OF EXPERIENCE.

Residence abroad.—Living in daily and hourly contact with his patients the sanatorium physician enjoys peculiar facilities not only for making and collecting clinical observations over a prolonged period of time and so of advancing our knowledge of the course and treatment of the disease in its manifold forms but through the social relationship which exists between himself and his patients he possesses unique opportunities which are denied to those engaged in medical and consulting practice of ascertaining the views of patients themselves upon the one matter which occupies their minds and attention to the exclusion of others—namely, the treatment of the disease. The information derived in this way from early cases whose first experience of treatment takes place at the sanatorium in quesion is of very minor importance but it is not so in the case of those whose search for health has extended over a period of several years and whose time has been spent abroad in large continental hotels and in districts the climate of which enjoys an established reputation in the treatment of lung disease. Many of these, after spending, it may be, one, two, or three seasons abroad, eventually land in one or other home sanatoriums. As a result of what they learn there and the "results" which they see around them they come to hold the view, rightly or wrongly, that if they had in the first instance been sent to a sanatorium instead of to a hotel they would long since have recovered their health. They had not been told anything to the contrary and they believed that the specific properties of the climate would secure their recovery. They had received no instruction regarding the nature of the life they were expected to lead and in consequence much of their time had been spent in pursuits which whilst they furnished a measure of enjoyment were carried on in surroundings which denied them that very atmosphere which they had gone to seek. Many of those patients hold the view strongly that if phthisical patients are not to be advised to enter continental sanatoriums then they ought to pass a preliminary period in some British institution in order to familiarise themselves with the principles underlying open-air treatment. They come to believe that if they are to derive full benefit from any climate *régime* is essential.

Prognosis.—Another point about which patients are apt to compare notes and to remark upon is the fact that the confident anticipation which had been held out to them that they would be quite well in three months had not been justified by events. From this they infer either that sanatorium treatment is not what is claimed for it or that the medical man had not fully appreciated the extent of the mischief in his case. As patients after they have entered a sanatorium find themselves surrounded by many convincing evidences of the efficacy of the life they are following I fear they more frequently make the second rather than the first inference. In this way the prestige of the medical man is apt to suffer in the minds of the patient. If experience of sanatorium life has taught the writer one lesson more than another it is the unwisdom of venturing to predict the duration of treatment which will be necessary to insure the complete recovery in any given case. In the type of instance here referred to the prognosis had of course been based chiefly or altogether upon the evidence of extent and distribution of the disease in the lung as revealed by physical examination. Early infiltration of one apex, it was assumed, clears up rapidly and a bilateral disease indicated a more prolonged term of treatment. Roughly that may be so but the exceptions are so numerous that he who follows the rule and prognosticates upon this basis will frequently find himself in the humiliating position of being called upon to explain to dissatisfied friends the disparity which has sprung up between promise and fulfilment. Experience has engendered caution. It is my practice now always to decline to express a definite opinion regarding prognosis in any case of phthisis until the patient has been under treatment for at least a month and I feel sure that if medical men in general would follow some such guarded course the charge that residence at sanatoriums sometimes interferes with that confidence which ought always to exist between patient and medical man would become practically unknown and much heartburning would be saved. There is much yet to be written upon the subject of prognosis in phthisis which has not yet seen the light and as it will probably form the subject of a future communication it need not be further referred to here.

Hill-climbing.—So far back as Brehmer's time emphasis was placed upon the special value of hill-climbing in the treatment of phthisis. Since then, however, there has arisen a school which holds a different view and which advocates that a patient should be kept at rest until the lung condition has completely cleared up. Experience here as to the comparative value of the two methods leads one to the strong conviction of the incomparable value of hill-climbing during convalescence when placed beside rest or even exercise on the flat. As a workable basis we have found that it is well to begin hill-climbing on a small way at an early point of the exercise stage. When the patient has reached a point where he is able to walk about six miles at a stretch without any marked temperature reaction appearing then the real hill-climbing is pressed. Latterly, it has been our practice to send the patient at least three times weekly, usually more frequently than that, a climb of about 1000 feet, with a long walk added. In many cases this is increased till it involves a climb of 1500 feet, the patient covering in all anywhere from ten to 20 miles at a stretch. The results obtained in such cases latterly have been so consistently good that one has come to be convinced that hill-climbing supplies a factor of treatment which is of cardinal value and, therefore, in selecting sites for future institutions this is a point to which the very greatest importance should be attached. The writer is hardly called upon to repeat the explanations which have already appeared so frequently elsewhere as to how hill-climbing operates in promoting recovery. But he is of opinion that it is right he should record the fact that his experience of its action has led him to believe that its systematic employment as an element of treatment is absolutely essential if the best results are to be obtained. There is, however, one class of apyrexial case in which he has found evidence that its use does harm rather than good. It should consequently never be pressed in cases of advanced chronic fibroid disease.

Diet.—So much has been done here in investigating the value of different diets and methods of dieting in tuberculosis that that part of the work might itself very well form the subject of a very extensive paper. But as it is unsuitable to deal with it fully now the writer will content himself by recording generally the teachings of experience. The very large diets which are associated with a certain German institution and which have come to be adopted in many quarters in Britain were at once found to be unnecessary and undesirable. Their application was invariably associated with marked dyspepsia and vomiting, weight, however, being usually gained under their administration. It was clearly demonstrated that in the vast majority of cases weight could be put on as fast and in some cases faster by a diet of more moderate amount when the proportion of the relative ingredients had received careful consideration than when a very large mixed diet was administered. In regard to fats, taken all over an average of two ounces of butter per day seemed to attain the best result and only in very few cases (six) where butter was badly borne did cod liver oil furnish a useful adjuvant or substitute. By presenting a larger variety of food and giving a smaller amount of each kind appetite has been well maintained and dyspepsia has become rare. In order to secure proper variety it has therefore been found to be an advantage to depart from the usual two or three course dinner and to give one containing a large number of courses and a moderate amount of each. Bread, butter, and milk in measured quantities suitable to each patient, however, accompanied all meals. In those cases of considerable pyrexia and marked signs of active disease the value of basing the diet given upon information obtained from metabolism investigation conducted in each case has been abundantly demonstrated. In passing it may be mentioned that the presence of various purin bodies in the urine have been found to furnish indications of special value in this line. The number of calories indicated was arrived at and a diet equivalent to that was fixed upon and written out. It has been found that by weighing each meal presented to the patient and the amount taken systematically day in and day out the patient's progress was more satisfactory than when he was placed upon an average diet. In some cases every meal taken has been weighed over a continuous period of six, seven, eight, and even nine months without intermission. Needless to point out this has entailed an enormous amount of work, but, as has been already said, the improvement in the results obtained has more than justified the expenditure of labour involved. The assistance rendered by the presence of a dental department established in the sanatorium over a year ago has been greater than was expected and has fully justified its presence. Since then dental defects present when a patient entered have at once been remedied before the treatment was begun. In a number of cases this factor seemed to have an important bearing upon the disappearance of dyspepsia which was hitherto present and the continuance of which would certainly have added to the difficulty of treating the cases.

The x rays and high-frequency currents.—The therapeutic value of high-frequency currents and the x rays as applied to lung disease still requires to be established but that both are extremely valuable adjuncts to treatment is a point upon which two years' close observation has abundantly shewn. High-frequency currents find their principal application in those cases of atonic dilatation of the stomach so difficult to treat successfully by other means and yet so commonly met with in phthisical cases. They are of further value in the neurotic type of patients and also in the various neuralgias accompanying the anæmia present in phthisis. A good deal has been written upon the subject of the Roentgen rays with regard to lung disease and no doubt in the near future much more will be done in this direction. It has been customary always to screen and to skiagraph our patients soon after admission after having previously formed an opinion by a careful physical examination of the conditions present, and it has frequently been one's experience to detect by this means conditions which had not been even so much as suspected previously to the x rays being used. Particular allusion is made to four cases of aortic aneurysm recognised within a period of 12 months by this means. As lavage is not infrequently employed in cases of gastric dilatation there were grounds for thankfulness for the revelation which enabled one to avoid what would have proved if adopted in these instances a dangerous procedure. All chests have been systematically examined by screening from time to time whilst patients are under treatment and one has found observations so made on the subject of changes at work in the lesions a matter at once interesting, instructive, and helpful in the matter of treatment. The value claimed for the x rays in the treatment of tuberculous glands has been fully confirmed by the observations made in the few cases which have come under notice. One case of lupus of 36 years' standing has cleared up under its use and at the present moment, over 12 months since the treatment was suspended, appears to be quite well. The x rays have also been applied in several cases of enlarged glands at the root of the lung. The results obtained in those cases, whilst not striking, have been at least encouraging.

Throat cases.—I am unable to give exact figures in regard to throat cases. All the cases of tuberculous involvement of the larynx that have come under my notice have been cases complicating pulmonary phthisis. Throats have been systematically examined and where necessary treated locally. In four cases distinct ulceration of the larynx healed under systematic local application of lactic acid and have remained well.

I gratefully acknowledge the valuable assistance I have received from Dr. Ian Struthers Stewart in compiling this paper.

Banchory, N B.

GEOGRAPHICAL DISTRIBUTION OF HARE-LIP AND CLEFT PALATE.

BY R. W. MURRAY, F.R.C.S. ENG.,
SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL.

I WAS anxious to obtain some information regarding the frequency with which hare-lip and cleft palate occur amongst the natives of different countries and last winter I wrote to a number of medical men in various parts of the world asking them their experience in this matter. I have received replies from China, India, Burmah, Straits Settlements, Java, Hawaii, Jamaica, and Central Africa, and as the information so kindly supplied to me may be of interest to others I give a brief account of the results of my investigations.

Dr. R. T. Booth of Hankow writes: "In my experience during five years' hospital practice in Hankow I have operated about six or seven times for hare lip. This, however, by no means gives an adequate idea of the frequency with which this deformity occurs amongst the natives. I should say that hare lip is common among the Chinese. In one day I counted four cases as I walked along the main street of this city. The Chinese do not pay much regard to their personal appearance; so long as the deformity does not interfere with their prospect of business success or of marriage they pay no attention to it. Hence the comparative infrequency with which such cases come under our care in hospital. Cleft palate, in my experience, is of rare occurrence; in none of my cases was there any deficiency of the hard palate, and while walking the streets I have sometime stopped and looked at the palate of a hare-lip case but there was no cleft of the palate in any I saw. In one case of hare-lip on which I operated there was an interesting condition of the soft palate and uvula. The formation of the hard palate was complete but there was a well-marked division of the soft palate and uvula: the portions of the soft palate were bridged over by mucous membrane only, which formed a transparent line down the middle of the soft palate; the uvula was bifurcated. This is the only case of any deficiency in the palate I have seen in China."

Dr. Robert Howard, writing from Lake Nyassa, Central Africa, says: "I have never seen an example of hare-lip or cleft palate amongst the natives on the shores of Lake Nyassa. I should be sorry to say that the deformity never occurs, for if it were a bad case the baby would probably die from inanition due to not being able to suck, or, again, the child might be put to death for some superstitious reason. I have never seen or heard of such cases and, so far as my experience goes, the deformity does not occur in this part of the world."

Mr. G. V. Lockett of Kingston, Jamaica, writes: "I have been at the General Hospital (200 beds) for about ten years and have seen only about 20 or 30 cases of hare-lip and cleft palate. All deformities are rare in this country. The people here are such a mixture that classification is impossible."

Mr. V. N. Chitale of Bombay writes: "Hare-lip and cleft palate are very common indeed in the Bombay Presidency and my friends tell me that this deformity is fairly common all over India amongst the different races."

Dr. Edward Armitage, writing from Hawaii, says: "Amongst the natives here I have never seen or heard of a case of hare-lip or cleft palate. I first came here in the summer of 1893."

Mr. G. W. Johnstone of Singapore says: "I have observed hare lip occasionally amongst the Malays and Chinese. I have never had a case to operate upon in any of the hospitals in the East which I have had charge of. On several occasions my offer to rectify the deformity was not accepted. A Malay is rather proud of a deformity and looks upon it as a mark of Allah's favour."

I also heard from Mr. S. J. D. Esser of Java who says that hare-lip and cleft palate are common deformities amongst the natives there. They do not consider the deformity any disadvantage and are seldom anxious to have an operation performed for it.

It is remarkable that hare-lip should be a comparatively common deformity amongst the natives of India, China, and Java and never be seen amongst the natives on the shores of Lake Nyassa or in Hawaii and the neighbouring islands. I believe it to be highly probable that hare-lip and cleft palate occur with varying frequency amongst all nations of the world and that the frequency with which it is seen amongst uncivilised natives depends very largely upon their religious belief, which would determine whether a child born with a hare-lip should be put to death or allowed to live. In an island such as Java where the deformity is not regarded with abhorrence but is looked upon with indifference, or possibly as a mark of Divine favour, one can well understand that as the result of frequent intermarriage hare-lip would become, as it is at present, of common occurrence. If, on the other hand, as is probably the case in Central Africa and some of the islands in the South Pacific, the mothers for superstitious reasons destroy their defective offspring, this would account for the deformity never being seen.

Liverpool.

CASES OF CONGENITAL DEFORMITY IN THE FŒTUS.

By H. CRIPPS LAWRENCE, M.D. Durh.,

AND

C. BRAINE-HARTNELL, M.R.C.S. Eng.

In the first of the two following cases what might be described as the principal abnormality consisted of hernia of the stomach, spleen, and intestines into the thoracic cavity. The case was that of a male infant who was born after a normal labour and respired at birth but exhibited cyanosis soon afterwards. When he was first seen by us the respiratory movements were chiefly abdominal. He was ordered a "mustard" bath which partially revived him. Dextrocardia was diagnosed during life, the heart pulsation being to the right of the right nipple line. The liver was in the normal position and enlarged. The lungs evidenced atelectasis, a little air entering at the right base and still less at the left base. There were resonance over the right half of the thorax and marked hyper-resonance over its left half. Death occurred 14 hours after birth.

A post-mortem examination was made of the contents of the thoracic and abdominal cavities. On removing the sternum the heart was found to be pushed over to the right side of the chest, the right ventricle being uppermost, the base of the heart pointing to the right of the right nipple line and the apex pointing to the left of the right nipple. The pericardium contained a few drachms of serum. Atelectasis adnata existed, the lungs being compressed on each side of the spine. The right lung was slightly inflated, especially its lower lobe; the left lung was still less inflated. The tissue of each lung floated in water. The left side and part of the right side of the thorax was occupied by the stomach, the whole of the small intestines, and the greater part of the colon. The spleen was found behind the stomach isolated and separate from the left suprarenal capsule, the latter with its corresponding kidney being in the abdominal cavity. The spleen had a deep cleft in it dividing it to its centre. The colon was continuous with its lower portion through a ring-shaped aperture in the left crus of the diaphragm. Below the diaphragm the upper two-thirds of the abdominal cavity was occupied by the liver, the left lobe of which was relatively small. The gall-bladder was distended with greenish bile. Beneath and below the liver the two kidneys, which were structurally normal, with their suprarenal capsules, were found some two inches below their proper position on each side of the spinal column. To the left of the spine were a small portion of the descending colon, the sigmoid flexure, and the rectum.

The second of the two cases, which was seen by only one of us (H. C. L.), was a female infant. It was stillborn and was expelled suddenly, the funis being ruptured. Inspection of the body enabled the following particulars to be noted. The length of the body was 17 inches. The circumference of the head was ten and a quarter inches; the antero-posterior diameter was four and three-quarter inches; the occipito-mental diameter was four inches; and the sub-occipito-mental diameter was three and a half inches. The occipital bone was very small; the large interval between it and the posterior fontanelle was closed by membrane. The anterior fontanelle ran down as far as the coronal suture, becoming continuous with the frontal suture, the whole hiatus being occupied by membrane. The right ear was malformed, having only a rudimentary helix and no concha. The left eyelid was arrested in growth, shortened, and closed. The thorax was contracted above and expanded below. The acromial end of each clavicle was prominent. There was well-marked "beading" of the ribs. The right forearm was pronated. The right thumb and forefinger were flexed; the middle finger was flexed across the forefinger. There was dactylitis of the first phalanx and the proximal end of the second phalanx of the ring finger, which with the little finger was straightened out. The left forearm was supinated. The left thumb was extended from the palm; the four fingers exhibited dactylitis; the phalanges [illegible] forefinger were extended, the upper end of the [illegible] being dislocated on to the palm; the remaining [illegible]xed. The umbilicus was occupied by a large [illegible]taining several coils of intestine; the sac measured four inches in circumference and two and a half inches from the abdominal wall to the fragment of funis at its lower end. The head of each femur was dislocated, the right more than the left, towards the thyroid foramen. The muscles of the arms and thighs exhibited indurations. The right tibia was curved and somewhat twisted, with the concavity on the inner side. The left tibia was more curved than the right one, with marked concavity on the inner side. The right foot manifested talipes equino-varus. The right big toe was in a line with the side of the foot; the next two toes were long; all three toes were separated from one another. The second toe was straightened; the two outer toes were shortened and flexed. The left toes were normal in length but the left little toe was deformed and curved under the sole of the foot. The genitals were normal.

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.

A CASE OF DIAPHRAGMATIC HERNIA.

(Under the care of Dr. Eustace Smith.)

For the notes of the case we are indebted to Mr. P. Stanley Blaker, late resident medical officer.

A male child, aged two years, was admitted to the East London Hospital for Children on June 16th, 1901, for diarrhœa and vomiting. The history elicited from the mother was as follows. The patient was taken ill suddenly with severe vomiting on the morning of June 13th, which persisted after each meal till admission into hospital. He also became very drowsy and feverish and started in his sleep every now and then. On June 11th and again on the 16th (the day of admission) the patient had an attack of diarrhœa, though during the intervening time the bowels appeared to have been normal. There was no history of any previous illness. The family history was good. On admission the patient was fairly well nourished but looked very pale and extremely ill. In bed he lay on his back, with his legs extended and in an apparently semi-conscious condition. The eyes were sunken and half-closed, showing the sclerotics. At times he screamed. The breathing was quiet and easy though hurried and there was no cyanosis. The pulse was rapid (about 120) and regular. The temperature was 105° F. in the rectum. There was no œdema. An examination of the chest revealed nothing abnormal in the heart or the lungs. The abdomen looked natural, moved with respiration, and was soft, though the patient somewhat resented palpation. The liver and the spleen were made out to be of normal size. The progress of the case may be briefly summarised as follows. On the day after admission there was marked tenderness of the abdomen, so much that the patient cried out whenever the abdomen was touched; this, however, became less evident later. The bowels had acted several times, the motions being green, slimy, and offensive. On the 18th some dulness and tubular breathing were detected over the upper lobe of the right lung posteriorly and a day or two later these signs of consolidation were also manifested over the front of the right chest. The vomiting ceased soon after admission and the diarrhœa also abated, but gradually. The temperature ranged between 102° and 105°. The left ear discharged pus freely. The general condition became worse and the patient died on the 23rd.

Necropsy.—The body was well nourished. The eyeballs were much sunken. The tongue, the fauces, and the œsophagus were natural. With regard to the thorax the upper lobe of the right lung was solid, voluminous, but not adherent. On section it presented greyish lobular areas of broncho-pneumonia. The middle lobe also had patches of

broncho-pneumonia but to a less extent. The lower lobe was shrunk to about a third
collapsed or airless nor
upper lobe of the left l
of broncho-pneumonia.
and was covered by a layer of lymph on the surface. There was thick green lymph scattered over the whole surface of the visceral and parietal pleura of the right lung, but there was no collection of fluid pus. As to the heart, there were a few flakes of lymph in the folds of the pericardium round the vessels at the base. With regard to the abdomen, behind the liver and immediately to the right of the œsophageal opening, was a diaphragmatic hernia. The tendon of the diaphragm was stretched out over the protrusion (there was no rupture of the tendon) in the right side of the chest and formed a sac of about the size of a large hen's egg. The mouth of the sac was not constricted and it contained about half of the stomach, including the cardiac and pyloric orifices, so that the finger could be passed straight into the sac from the œsophagus or from the duodenum Most of the greater curvature of the stomach was outside the sac. There were no adhesions and the hernia was readily reduced. There was also some omentum in the sac. The stomach and the intestines were natural. The liver was fatty; the spleen was natural; the kidneys were pale and showed some cloudy swelling. The brain and the meninges were healthy.

Remarks by Mr. BLAKER.—A diaphragmatic hernia is a sufficiently rare condition to merit publication of the above case. Two varieties of diaphragmatic herniæ are described —one the congenital (or true) and the other the acquired (or false). In the former the abdominal viscus passes through either a deficiency in the structure of the diaphragm or through one of the natural openings which may be unusually large. Such openings may be the œsophageal or one of the fissures situated between the sternum and seventh costal cartilage in front or between the lumbar and costal attachments of the diaphragm behind. Sometimes, however, a portion of the diaphragm seems to be weakly developed and yields before a hernial protrusion. This bulging occurs more often in the muscular portion of the diaphragm. In the latter variety (acquired), which is by far the commoner (about 10 to 1), the hernia is nearly always due to an injury which tears through the diaphragm and allows the abdominal viscus to escape in practically every case without a peritoneal covering. Both varieties are said to occur mostly on the left side—i.e., the protrusion takes place into the left side of the chest—the pleura being either torn through or else carried before the hernia. The presence of the liver on the right side is held responsible for this greater frequency of herniæ on the left side. The organ most commonly displaced is the stomach, next in frequency is the transverse colon, and then follow the omentum, the small intestines, the spleen, the liver, the pancreas, and the kidneys in the order named. Considering these few facts it will be seen that the case recorded was not altogether of the usual type. The hernia was of the congenital variety; the outer sac was formed by a bulging in the tendinous portion of the diaphragm and was on the right side in spite of the presence of the liver.

I am indebted to Dr. Eustace Smith for permission to publish the notes of the case.

ROYAL ALBERT HOSPITAL, DEVONPORT.

PERFORATED DUODENAL ULCER; OPERATION; RECOVERY.

(Under the care of Dr ALONZO G. RIDER.)

FOR the notes of the case we are indebted to Mr. H. M. Major, assistant house surgeon.

The patient, a male, aged 44 years, was at 12 30 P.M. on Jan. 8th, 1904, seized with acute epigastric pain immediately after swallowing a piece of beef. He was seen by Dr. Rider at 1.30 P M. who found him in great pain and much collapsed. There was extreme tenderness over the whole abdomen, especially in the epigastric region. Liver dulness was present. One-sixth of a grain of morphine was given and hot water bottles were applied to the feet. He was seen again at 4 P M when the collapse had partially passed off. The pain was much more severe and more generalised. Bilious vomiting which did not relieve the pain was frequent. Liver dulness was then indistinct and fixation of the abdominal muscles in the upper part of the abdomen was commencing. Dr. Rider ordered his immediate removal to the hospital but delay occurred and he did not arrive till 7.30 P.M.

The following history was given. The patient had suffered on and off for the past three years with pain after food and occasional vomiting The pain, which came on at short intervals after a meal and was referred to the epigastrium and occasionally to between the shoulders, was relieved by vomiting. He had obtained considerable relief by dieting himself. There was no history of hæmatemesis but he had remarked on the very dark (tarry) appearance of his motions. There was a history of constipation for some years. For the past three weeks there had been a considerable increase in the amount of pain which persisted after vomiting. The pain was so severe at times that he had been unable to eat anything, though he managed to continue his work. On Jan. 7th when he returned from work he was unable to eat any supper and on the 8th his breakfast consisted of a couple of dry biscuits. He went to work but was in considerable pain and on returning home at mid-day had just started his dinner when the violent attack of pain commenced.

On admission he was extremely collapsed. The temperature was 97° F. The pulse was 112, thready, and at times almost imperceptible. A hypodermic injection of five minims of liquor strychninæ was given at once. The whole abdomen, especially in the upper part, was absolutely rigid. There was no abdominal distension and the percussion note was apparently normal. There was increased diminution of the liver dulness Immediate operation was decided on and measures were taken to minimise shock.

The patient was anæsthetised by Mr. H. M. Major (chloroform and ether being used), and assisted by Mr. J. J. N. Morris the abdomen was opened by a five inch incision between the xiphisternum and umbilicus (on reaching the subperitoneal fat it bulged forward, giving the appearance of a knuckle of small intestine presenting in the incision). On opening the peritoneum free gas escaped as well as a small quantity of greenish turbid fluid from a pouch in the gastrocolic omentum. On drawing up the stomach into the wound a quantity of similar fluid escaped from the neighbourhood of the pylorus and on further examination a perforation foureighths of an inch by three-eighths of an inch (the long axis being transverse) was found on the anterior surface of the first part of the duodenum. There was a considerable amount of indurated tissue surrounding the ulcer. The perforation was temporarily closed by a gauze swab and systematic sponging of the whole of the abdominal viscera was undertaken, followed by irrigation with many pints of normal saline solution. No solid pieces of food were discovered but some flakes of recent lymph were removed from the viscera in the neighbourhood of the perforation. Suturing was performed with difficulty partly on account of the friable nature of the surrounding tissue and partly owing to the depth of the intestine (it was not considered necessary to divide the right rectus). A purse-string silk suture surrounding the perforation was first passed, followed by several interrupted Lembert sutures. A quantity of saline solution was left in the peritoneal cavity and a drainage-tube was passed down to the duodenum.

The patient stood the operation well and during its performance was given a hypodermic injection of five minims of liquor strychninæ and an enema of five ounces of hot coffee and one ounce of brandy. The enema was ordered to be continued every four hours and the strychnine every two hours until toxic symptoms showed themselves. Twitchings occurring at 1 A M (he having then had 20 minims in five and a half hours) the injections were stopped for four hours and then three minims were given every four hours. No further trouble occurred with the injections. Four hours after his return to bed he vomited a small amount of green frothy fluid and this continued at half-hourly intervals until 8 A.M., the total amount being five ounces. After a hypodermic injection of a quarter of a grain of morphine sulphate and $\frac{1}{150}$th of a grain of atropine sulphate he vomited once only.

On Jan. 9th the patient had a fair amount of sleep. The temperature was 98°, the pulse was 82, and the respirations were 20. The first dressings were slightly stained with serous fluid. The abdomen moved well with respiration. Nutrient enemata of white of three eggs, four ounces of peptonised milk, one ounce of raw starch, and half a drachm of salt were ordered every six hours in place of the coffee and brandy. In the evening the temperature was 99·2°, the pulse was 82, and the respirations were 22. The dressings were very slightly stained. The patient complained of thirst, for which mouth washings with hot water were ordered and a pint of saline solution by the rectum. There was some pain on inspiration under the right costal arch. On the 10th the temperature was 98°, the pulse was 68, and the respirations were 20. He was at first restless during the night but slept well and woke refreshed after a hypodermic injection of a quarter of a grain of morphine sulphate and $\frac{1}{100}$th of a grain of atropine sulphate. The strychnine injections were stopped. The wound looked perfectly healthy. There was some increased amount of discharge. The pain under the ribs was less. In the evening the temperature was 99·6°, the pulse was 76, and the respirations were 22. He felt comfortable. On the 11th the patient had passed a good night and looked distinctly better. The temperature was 98°, the pulse was 72, and the respirations were 20 There was practically no discharge; the tube was left out and a wick of cyanide gauze was substituted. The pain under the ribs had quite gone. He was given sips of hot water (half an ounce) every two hours. The bowels opened naturally and the motion was normal in appearance. On the 12th he had had a good night. He felt and looked very well. He was given ten minims of bovinine and water to one ounce every two hours. On the 13th the bovinine was gradually increased to one drachm and alternated with one ounce of peptonised milk every two hours. The nutrient enemata were stopped. The further progress of the case was quite uninterrupted. The patient was gradually put on full diet and left the hospital at the end of a month for the convalescent home feeling quite well.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

The Value of the X Rays in the Diagnosis of Early Pulmonary Tuberculosis. The X-ray Treatment in Recurrent Cancer of the Breast.

A MEETING of this society was held on May 13th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. A. S. GREEN (Lincoln) and Dr. W. H. B. BROOK (Lincoln) communicated a paper upon the Value of the X Rays as a Factor in the Diagnosis of Pulmonary Tuberculosis which was illustrated by lantern slides. The object of the paper was to demonstrate the use of this method of diagnosis in the early stages of the disease. That the full value of the x-ray examination might be obtained it was absolutely necessary to compare the evidence derived by this method with that elicited by careful examination of the physical signs and by a microscopical examination of the sputum. It must be definitely laid down that the Roentgen rays were only to be used as an adjunct to the usual methods of examination and could never replace these latter. Dr. Green had examined and photographed during the past two and a half years a large number of patients, in nearly every one of whom the physical signs had been carefully examined by Dr. Brook. X-ray photographs taken at various intervals both before and after sanatorium treatment were exhibited and the physical signs were narrated. In some cases where the physical signs had entirely disappeared under treatment the shadows were absent from the second plate; in others where the patient had made great improvement but the physical signs had not entirely disappeared the shadows had altered in character; in others again, in spite of the patient's improvement and the disappearance of the chief physical signs, the plates taken before and after treatment were identical both in density and extent. The examination must be carried out by both screen and plate methods. By means of the former the following points could be noted: (1) the height and movement of the diaphragm on the two sides both in quiet (minimum) and forced (maximum) respiration, and these must be compared in front and behind, it having been shown that where the disease was more active or extensive the level of the diaphragm would be higher and the movements more curtailed and that unilateral limitation of movement of the diaphragm was one of the earliest signs of pulmonary tuberculosis; (2) the position and size of the heart, the shape and slope of the ribs and the width of the intercostal spaces; and (3) the transradiancy of the lungs and the effect upon this of inspiration. This examination could be carried out with the patient standing up or (preferably) lying down on a table with a vellum top and a tube below freely moveable in both directions. The skiagrams exhibited had all been taken by the plate-to-back method with the tube from 20 to 24 inches from the plate. The exposure had varied from 30 to 60 seconds. Development should be very thorough and should always be carried out by the medical man himself instead of being left to chemists and photographers, as much could be learnt during the process of development which was not so apparent when the plate was fixed.—Dr. W. EWART congratulated Dr. Green and Dr. Brook upon their paper and remarked on the value of the movements of the diaphragm and of the ribs in the early diagnosis of pulmonary tuberculosis.—Dr. C. THEODORE WILLIAMS did not quite agree with the statement that cavities, excepting very minute ones, could not be diagnosed by auscultation. Modern auscultators were not perhaps as careful as those of a previous generation. Some cavities might be difficult of detection but were readily diagnosed if the patient were made to cough.—Dr. G. B. BATTEN considered that as a means of realising more vividly the physical condition than was, perhaps, possible by auscultation the x rays were to be welcomed in the diagnosis of phthisis, also for recording the progress of the disease in its different stages. Skiagrams were useful both to the patient and to the medical man.—Dr. H. S. FRENCH inquired as to the extent of fibrous tissue which could be seen in a skiagram and how it could be distinguished from tuberculous deposits.—Mr. C. R. C. LYSTER asked what methods were adopted for measuring the output of the tube and also if the x rays could be utilised to distinguish between bronchitis and tuberculosis. A thickened pleura also presented difficulty.—Dr. WILLIAM PASTEUR inquired as to the relative transparency to the rays of enlarged bronchial glands and whether fluid in the pleural cavity could be seen to vary with the position of the patient.—The PRESIDENT considered that ocular demonstration of the morbid condition was most valuable but at the same time shadows were not always infallible and required to be interpreted with care. Post-mortem records of cases so examined would be very valuable.—Dr. GREEN and Dr. BROOK replied.

Dr. E. A. PETERS (introduced by Mr. CHARTERS J. SYMONDS) described two cases of Recurrent Carcinoma of the Breast treated by the X Rays. In the first case the original operation had been performed by Mr. Symonds. The treatment was pursued for 22 months; the subcutaneous nodules and ulcer disappeared under the treatment. They returned on cessation of the treatment but in a condition of diminished activity. Eventually growths appeared subcutaneously at the back of the thorax. These again nearly disappeared on treatment. Unfortunately the operation cicatrix broke down during an attack of dermatitis and caused a large ulcer which persisted to the patient's death in the twenty-second month of treatment from thoracic involvement. Meanwhile the other breast and the subcutaneous structures and glands of the other wall of the thorax became involved. The supraclavicular glands became affected while the supraclavicular region was exposed to the x rays. The patient found in the x rays great relief from pain but suffered from the ulcer and pressure on the nerves. In the second case subcutaneous nodules and pleuritic thickening improved very considerably under a month's treatment. The patient died shortly afterwards from thoracic involvement. There seemed to be a tendency for scar tissue to break down under the influence of the x rays.—Dr. H. LEWIS JONES said the question of the treatment of malignant disease by the x rays was one of the highest importance. The treatment had a most undoubted and beneficial effect upon superficial deposits and ulceration. But it was most disappointing to find cases die from internal deposits while under treatment. Locally there was success, remotely there was failure. The solution of this problem afforded opportunity for much speculation. But as a practical point x-ray treatment should be applied much earlier than it generally was; the treatment might be employed immediately after operation. There was no doubt that the rays possessed the property of changing the characters of a growth or even of preventing its tendency to recur.—Dr. BATTEN referred to a case of recurrent cancer of the breast in which the nodules had been removed by operation as fast as they had recurred but upon the seventh occasion he had exposed the part to the x rays with the result that the nodules had completely disappeared, the patient ultimately dying from an intercurrent malady. The x rays appeared to have a selective effect both upon degenerating and also upon actively growing epithelial cells. Some dermatitis must ensue to produce a beneficial effect. The occurrence of internal deposits suggested the possible liberation of toxins by the superficial treatment.—Dr. A. E. T. LONGHURST asked whether the rays might not at times excite the local condition and so give rise to a rapid development of the disease.—Mr. A. A. BOWLBY had no doubt whatever that the x rays were by far the most potent agent at their command for the treatment of recurrent cancer of the breast superficially situated. On the other hand, they might produce considerable inflammatory reaction, as in a case he mentioned which died from cellulitis of the neck.—Mr. LYSTER expressed the opinion that excision was still the best method of dealing with cancer when it was discovered early enough but that in inoperable cases relief of pain, comfort to the patient, and removal of recurrent nodules could be brought about by the rays.—Dr. PETERS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE

Poisoning by Cantharides.—Poisoning by Coal Gas and Carburetted Water Gas.—Duties of Medical Men at Coroners' Inquests.

A MEETING of this section was held on April 22nd, Sir JOHN W. MOORE, the President of the section, being in the chair.

Dr. F. C. MARTLEY brought forward a case in which an elderly woman had been Poisoned by Cantharides. About an ounce of the powdered drug had been administered to her in a glass of rum but in spite of the amount having been so large she survived for 31½ hours.

Professor E. J. MCWEENEY read a paper on the Cases of Poisoning by Coal Gas that have occurred in Dublin since the addition of carburetted water gas to the ordinary coal gas. He said that the first person to draw attention to the increased percentage of carbon monoxide in the Dublin coal gas was Professor Emerson Reynolds who, in a paper read before the Royal Dublin Society in 1900, communicated the result of a number of analyses made by him which went to show that the ordinary percentage of carbon monoxide—namely, 6 per cent.—had been more than doubled during February and March, 1900, and this increase he accounted for by the addition of carburetted water gas. Some recent analyses made by Mr. Holmes Pollok, of the Royal College of Science, showed the presence of 17 2, 16 8, and 14 6 per cent. of carbon monoxide. Professor McWeeney then proceeded to recount in detail the circumstances attending the seven fatal cases that had come under his notice during the past three years. Special features of interest attached to each. In the first group the family of four lived in a house where gas was not used and there were no fittings. The gas had penetrated into it from a broken main in the street with the result that one of the persons was found dead and the others were more or less collapsed. The hæmoglobin in the fatal case contained much carbon monoxide. In the second group an attempt had been made to defraud the gas company by leading the gas into the house without it passing through the meter. The indiarubber tube used in the attempt had slipped off, with the result that the family of three persons were asphyxiated in their sleep. The third group of cases was that of a man and his wife who were suffocated in a bedroom at a Dublin hotel by gas escaping from a wall-bracket the stop-cock of which was half open. The last case was that of a young man who was asphyxiated in his bath by the carbon monoxide contained in fumes escaping from a badly constructed and unventilated "geyser." The hæmoglobin in this case was loaded with carbon monoxide.—Professor C. R. C. TICHBORNE said that in the last case it was evident that the carbon monoxide did not come from the combustion of the gas, as it would then have been converted into carbon dioxide, but must have got into the room as carbon monoxide. He suggested that as the accident had happened about 9.30 P.M., a time when there was great pressure in the mains, the carbon monoxide might have escaped through the air inlets in the Bunsen burners.—Mr. O'CONNELL J. DELAHOYDE said that in his opinion a good deal of the ill health among the working classes was to be put down to the use of penny-in-the-slot meters and gas cooking stoves which were not connected with a flue.—Dr. T. P. C. KIRKPATRICK said that it seemed remarkable that carbon monoxide gas was escaping at such a rate as to accumulate in a man's hæmoglobin and to poison him without exploding though the gas jet was lighted all the time.

Dr. MARTLEY read a short paper on the Duties of Medical Men at Coroners' Inquests, a subject that had been suggested by events which had been reported by the press to have occurred at a recent inquest. It appeared that a man had been taken dead into a hospital at which he had attended as an out-patient more than six months previously. The coroner asked the house surgeon to give his opinion as to the cause of death without making a necropsy. This he declined to do, whereupon the coroner directed the jury to find a verdict. The following motion was adopted unanimously by the section:—

> Resolved: That the Council of this Section be requested to communicate to the Council of the Academy the facts relative to the case in which one of the Dublin coroners recently called upon a member of the medical profession to certify to the cause of death of a patient who was brought dead into the Royal City of Dublin Hospital, with a recommendation that those facts, as well as the relation of the profession to coroners' courts, should be brought under the notice of the authorities.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A meeting of this section was held on April 29th, Dr. H. C. EARL, the President, being in the chair.

Dr. T. G. MOORHEAD showed three slides in which the Leishman-Donovan Bodies appeared, giving a description of the cases from which they were taken and a history of the discovery of the bodies and their relation to malaria.

Professor E. J. MCWEENEY showed specimens of Blood from a case of Pernicious Anæmia exhibiting Punctate Basophilia. Many of the red corpuscles were thickly sprinkled with granules of strongly basophilic character which could be detected in preparations stained by Jenner's and Pröscher's modifications of Romanowsky's stain, as well as in triacid preparations. He was inclined to look upon the granules as due to karyorrhexis.

Professor MCWEENEY showed slides of Rabbit's Blood containing the Nagana Parasite; also of Human Blood containing the Parasite of Sleeping Sickness. These latter had been given to him by Dr. W McCarthy, travelling scholar in pathology of the Royal University of Ireland, who had obtained them from the Pasteur Institute where he had been working.

EPIDEMIOLOGICAL SOCIETY.—The last meeting of the session of this society was held on May 13th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. Moritz Pistor, Principal Medical Officer to the Ministry of Religion, Education, and Public Health of Prussia, read a paper on the Prevalence of Enteric Fever in Prussia during the ten years 1892 to 1901, with remarks on the etiology and prevention of the disease. After a brief retrospect of the history of the recognition of a *febris pestilens* by Willis and Sydenham and of the differentiation of typhus fever and enteric fever by Hildebrand and Murchison 50 years ago he proceeded to trace the diminution in the mortality from enteric fever from an average of over 6 to less than 2 per 10 000 of the population throughout the kingdom during the last quarter of a century, though admitting that owing to the habits of the people in the less advanced provinces, especially where the population was mainly Polish, the registration of the causes of death was imperfect and the notification still more so, many cases of illness not being medically attended, so that he would not attempt to estimate the morbidity or the fatality on such defective data. The reported death rates in the various districts year by year were shown in a table and illustrated by a coloured map. In the analysis of these death-rates it seemed impossible to fix on any single condition—climatic, orographic, or geological, or connected with the industries—as the chief factor. Districts having everything in common had high or low mortalities and others differing in every respect had the same, the habits of the people themselves being of the greatest importance. The highest mortalities were in Trier on the Moselle, near to the French frontier, with hot summers and mild winters, closely followed by Arnsberg, also in a mountainous country, with a mining and industrial population, and Dantzig lying low on the sea coast but with colder winters. Lower but still above the mean came the vast plains from Dantzig to Königsberg, devoted to agriculture, and Aachen, Magdeburg, Coblentz, and Hildesheim west of the Elbe and for the most part industrial. Below the mean were Nassau, close to Arnsberg, with a continental climate and mainly agricultural; Hanover, with the exception of Hildesheim, industrial in the south but agricultural and maritime in the north, with Holstein and Schleswig of like character; the wealthy residential town of Wiesbaden; and Berlin, the metropolis of the kingdom and empire. Aurich on the North Sea, including several islands, had the lowest mortality from enteric fever and diphtheria. Lower Silesia with the district of Oppeln, which had an evil reputation for its general sanitary conditions, in constant communication with Austria and Russia, was, strange to say, below the average, while on the other hand Stralsund, in the otherwise healthy district of Pomerania, remarkable for the cleanliness of its peasantry, showed a high mortality which, however, was accounted for by the inclusion of deaths in the University Hospital of Greifswald, for the water-supply was unimpeachable. The low death-rate in Upper Silesia and the Westphalian coalfields was explained by the general provision of excellent public supplies after the wells in the locality had been drained or rendered undrinkable through the mining operations in recent years. The excessive prevalence of enteric fever in the eastern provinces, whether agricultural or industrial, was connected with the apathy and disregard of all hygiene by the Polish population, the Poles being incorrigibly dirty. So, too, in the mining districts of Arnsberg and parts of Westphalia the miners were very largely foreigners and immigrants, French Walloons, Poles, Italians, and even Roumanians. Even in the German population, however, miners as a class were deficient in the sense of order and cleanliness, drawing their water from wells and watercourses which they had polluted with excreta and sewage and living in a state of overcrowding. As a rule the sanitary conditions of Saxony and the Rhine provinces were good, while the pure German populations of Hanover and Schleswig-Holstein were from their excellent sanitary surroundings and prosperous circumstances the freest from enteric fever. Dr. Pistor having discussed the views of Murchison and Budd and of Buhl and von Pettenkofer on the etiology of enteric fever expressed his belief with Koch that the bacillus was incapable of maintaining its existence in the soil and even of retaining its vitality for many days out of the human body. Sudden outbreaks and epidemics were mostly caused by accidental pollutions of water-supplies and milk-supplies, while other articles of food and direct personal infection were the ordinary vehicles in the sporadic forms of the disease, unrecognised cases or those that were so mild as not to inspire alarm playing a more important part in the ordinary spread of the disease. He referred to the Gruber, Conradi, and von Drygalski's serum and other methods of diagnosis, but considered that they could be relied on only in the hands of experts. If, however, every case were reported and traced to its source the assiduous carrying out of every sanitary precaution would in course of time bring enteric fever, like cholera, into the class of what he might call "travelling diseases."

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on May 12th, Dr. Thomas Richmond, the President, being in the chair.—Mr. R. H. Parry exhibited amongst others the following specimens and read notes of the cases from which they were removed. 1. A prostate removed by Freyer's method. This was removed complete in 15 minutes, only a thin outer layer of the gland being left adherent to the recto-vesical fascia; the removal of this outer layer was considered inadvisable as its absence would have permitted of extravasation of urine into the pelvis. The prostatic urethra was removed along with the gland. 2. A Foreign Body removed from the œsophagus by œsophagotomy. It was a piece of coal which had been introduced into the gullet with suicidal intent. The operation was the second one performed for a similar condition in the same patient who after this operation, from which he made a good recovery, was removed to an asylum. 3 A specimen from a case of Complete Gastrectomy. The patient, who was a woman, was sent to the Victoria Infirmary in April, 1902, by Dr. A. A. F. Steen. Until three months prior to admission she had suffered from weakness and giddiness with progressive emaciation; she had no gastric symptoms up to this time when she suffered from pain and sickness, weakness and anæmia. A swelling was discovered in the "pit of the stomach" two months before operation. When admitted to hospital she was in a very low condition, the emaciation being extreme, and Mr. Parry had great doubts as to the advisability of any operative procedure at all but she made continual appeals to him "to do something." The abdomen was opened in the middle line and the stomach was examined; it was found to be very small, with a considerable carcinomatous tumour involving the pylorus and extending along the lesser curvature almost to the cardiac end of the viscus. The whole was removed, the duodenum with the head of the pancreas being carried over to the left side and stitched to the œsophagus by end-to-end approximation. The operation was hurriedly completed owing to the serious condition of the patient, the parietes, which consisted practically of skin and peritoneum (so great was the emaciation), being speedily brought together. On the day following the operation a portion of bowel protruded from the wound and this gave rise to some little disturbance, but thereafter the patient recovered gradually, food being taken by the mouth on the fourth day after operation. She was shown to the society and declared herself to be feeling very well. She was able to work and to take food fairly well, her breakfast usually consisting of an egg, toast, and tea and her dinner of a little butcher's meat and potato. Fish she declared did not agree well with her. She sometimes suffered a little pain but constipation, which had been a marked feature of the case prior to the operation, now troubled her very little. She looked remarkably well. 4. A specimen of the Middle Third of the Anterior Wall of the Stomach removed for cancer 18 months ago, the tumour also involving the transverse colon. The patient was now alive and well.—Mr. Parry read notes of another case of Complete Gastrectomy which did well for seven days when, owing to the yielding of some of the sutures, complications supervened which terminated fatally. He also showed specimens from two cases of Pylorectomy and two cysts of the Pancreas, the removal of which was followed by recovery. He said that these cysts were generally found about the tail of the pancreas and were, as a rule, mistaken for floating kidney; an important point in the diagnosis of this condition was that the right kidney was the one usually found to be moveable, and even after its reposition a small part of it might still be palpable, but in the case of the left, after replacement no part of the kidney should be palpable and where something was felt in the left loin in these circumstances strong suspicion should be entertained of the presence of a pancreatic tumour.—Dr. J. Lindsay Steven, Dr. T. K. Monro, Dr. Carstairs C. Douglas, Dr. D. Macgilvray, and the President took part in the ensuing discussion.

EDINBURGH OBSTETRICAL SOCIETY—A meeting of this society was held on May 11th, Dr. N. T. Brewis, the President, being in the chair.—Dr. F. W. N. Haultain read a paper on Malignant Uterine Complications of Fibro-myomata. He described cases and exhibited micro-photographs of specimens showing distinct sarcomatous degeneration of fibro-myomata with recurrence after removal. He had found four cases of malignant degeneration out of 1200 collected cases of fibro-myoma. He discussed the question of panhysterectomy as compared with the supravaginal method of treating the stump after removal of the uterus with fibro-myomata. The latter operation had a considerably less mortality in the hands of most operators and was therefore to be preferred, as the risk of possible malignant degeneration of the cervical stump was much less than the extra risk of the mortality in panhysterectomy. He considered that fibroids which produced no symptoms should be left alone as the risk of their removal by operation was much greater than the possible risk of malignant degeneration if left without operation.—Professor A. R. Simpson, Dr. James Ritchie, Dr. J. H. Ferguson, and others discussed the paper.—Dr. J. W. Ballantyne read a paper entitled "The Obstetric Satchel: a Problem in Asepsis." With respect to the intra-uterine use of antiseptics he said that it was better to prevent the access of pathogenic organisms to the uterus than to pursue them with antiseptics after they were there. By a germicidal action of the vaginal mucus and possibly by other protective mechanisms of a more complex kind, microbes introduced into the vagina from without were rendered innocuous. The gush of liquor amnii, practically a normal saline solution, helped to wash away any microbes which the vaginal mucus (perhaps becoming scanty) had failed to kill. The placenta, like a huge sterilised sponge, swept through the vagina, carrying clots, shreds of membrane, meconium, vernix, and all such putrescible matter before it. Outside the vaginal orifice, however, there were congregated multitudes of pathogenic and pyogenic organisms which might be carried in on the examining finger, on instruments, or on the douche nozzle, and near the anus there was the bacillus coli communis which was greatly to be feared in its later developments. Obstetricians disinfected the vulva lest fingers, instruments, or douche might receive contamination on entering the vagina. The accoucheur's hands were carefully prepared and the necessary instruments were boiled in maternity hospital practice and to some extent in private practice, but the ordinary obstetric bag was a weak point. The bag with detachable lining was an improvement, although it fell short of the requirements necessary for a surgical operation, as an ovariotomy. Dr. Ballantyne showed an obstetric bag of enamelled iron trays, &c., suggested by Professor Edgar of New York. He then described his modification, which he designated a satchel. It consisted of two trays made of tinplate, the one to fit into the other but not completely; the larger measured 17 inches by 7½ inches by 6 inches; the other was less deep. In the space between these the bottles of chloroform, ergotin, ether, douche tubes, &c., were contained in a cotton hold-all with many compartments. The various obstetric instruments were each in linen bags, all previously sterilised. A sterilised coat or apron was carried in sterilised towels. The two metal cases could be used as trays for washing the hands or for sterilising instruments over a fire. The whole was covered with a brown canvas cover which acted as a carrier. There was no rattling noise in carrying it.—Dr. G. L. Chiene, Dr. A. D. Webster, and others discussed the paper.—Professor Simpson showed a Commemoration Plaque of the Fiftieth Anniversary of the Foundation of the Obstetrical Society of Leipsic.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on May 11th, Dr. E. S. Reynolds, the President, being in the chair.—Dr. J. Dreschfeld and Dr. F. Craven Moore described three cases of Primary Sarcoma of the Liver. 1. A female, aged 56 years, suffered for four months from gastric disturbance, pain in the hepatic region, abdominal tumour, loss of weight, jaundice, and towards the end from ascites. At the necropsy the liver was found to be occupied by a large single mass of new growth; the peritoneum and the cœliac and mediastinal glands were the seat of metastases. In structure the new growth was a sarcoma, round- and spindle celled, probably arising from the endothelium of the portal capillaries. 2. A male, aged 23 years, suffered for five months from weakness, wasting, and abdominal tumour. There was no ascites or jaundice. The necropsy revealed a diffuse infiltrating new growth of the liver, with metastases in the portal glands. In structure it was a typical endothelioma of the portal capillaries 3. A male, aged 61 years, suffered for five months from weakness, wasting, and abdominal tumour. No jaundice was present. Ascites occurred towards the end. At the necropsy the liver was found to be occupied by a number of nodules of new growth, the larger of which were cystic. In structure they were angio-sarcomata undergoing myxomatous degeneration.—Dr. Charles H. Melland and Dr. D. Orr gave a lantern demonstration of coloured micro-photographs illustrating the morphology of the malaria parasite.—Dr. R. T. Williamson showed specimens of a Small Sarcoma of the Cerebellum affecting the left amygdala only. The symptoms had been chiefly headache, vomiting, double optic neuritis, and ataxia with a tendency to fall to the left. Marchi's method of staining revealed marked degeneration of the posterior root fibres in their intramedullary course in the upper half of the spinal cord. There was marked degeneration in Burdach's columns in the cervical region but Goll's columns were unaffected.—Dr. Williamson also showed specimens from the brain of a patient who had suffered for 12 months from intense headache. There was no optic neuritis until the last four days of life. Four tuberculous masses were present in the cerebrum, all of which were surrounded by a thick fibrous capsule. The masses resembled gummata but their tuberculous nature was shown conclusively by the presence of numerous tubercle bacilli.—Dr. I. Walker Hall showed an Intrapericardial Aortic Aneurysm communicating with the pulmonary artery and left auricle.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—The closing meeting of the session of this society was held on May 9th, Mr. A. E. Maylard, the President, being in the chair.—Mr. G. B. Buchanan showed the Sac and Coverings of an Umbilical Hernia with omentum adherent round a large part of the wall from a patient 71 years of age, operated on for strangulated hernia.—Dr. A. Napier showed a patient, the subject of very extensive Lupus Verrucosus, who was under treatment by curetting, actual cautery, and injections of tuberculin; there had been marked improvement since this treatment was commenced. —Mr. Buchanan also showed a specimen of Epithelioma of the Œsophagus which had penetrated into the larynx.—Dr. Napier read notes of a case of Acromegaly in a woman, aged 34 years. The condition had been slowly advancing for five years. A series of photographs and the patient were shown.—Dr. J. Wainman Findlay read notes of a case of Chronic Lymphatic Leukæmia and demonstrated the condition of the blood. The patient was 60 years of age. The enlargement of the glands under the chin was noticed two years previously and now all the superficial glands were greatly enlarged. The proportion of leucocytes to red corpuscles was about 1 to 2 5 and the small lymphocytes formed 96 per cent. of the first-named. The red blood corpuscles numbered 1,424 000 and the white blood corpuscles 568,660 per cubic millimetre. The patient had had syphilis 35 years ago and malaria some time later.—Dr. T. K. Monro and Mr. J. Archibald Campbell reported a case of Splenic Abscess and Empyema due to the Bacillus Typhosus and associated with a positive Widal's reaction but without intestinal lesion. Except fever the case showed none of the signs of enteric fever. The case terminated fatally in about three weeks.—Mr. R. H. Parry showed a case illustratin Brophy's Operation for Cleft Palate.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on April 28th, Dr J. H. Stowers, the President, being in the chair.—The following cases were exhibited: Dr. Alfred Eddowes: (1) A case, aged 20 years, of Lichen occupying nearly the whole of the body covered by clothing; and (2) microscopical specimens from a case of Acute Eczema.—Dr. E. G. Graham Little: (1) A case for diagnosis; the
philis, ? Tubercu-
Ulcer; (3) Lichen
pertrophicus with
on the Lip with
mma of the Left
of the Lobules of
Both Ear
ago.—Dr.
D. Savill
Morphœa
and (5)
(1) A sma
Dr. E. Stainer: Localised Atrophy of the Skin.—The President: (1) Alopecia Neurotica Universalis; (2) Eczema Pustulosum of the Hands; and (3) photographs of a case of Hydroa Herpetiforme —Dr. Wilfrid B. Warde: Persistent Œdema of the Hand and Forearm.

LEEDS PUBLIC DISPENSARY.—Professor Clifford Allbutt who for many years was closely associated with the Leeds Public Dispensary, opened the new buildings of that institution in North-street, Leeds, on May 12th In the course of a very interesting address Professor Allbutt dwelt upon the splendid victories which the healing art had achieved. Typhus fever and other diseases, he said, had become rare or had disappeared, pulmonary consumption had been reduced, and the extraordinary discovery of the nature of malaria had changed or would change the face of vast fertile areas which had hitherto been almost uninhabitable. With these changes going on they might hope that charitable institutions such as the Leeds Dispensary would not need to be enlarged continually in the future as they had in the past. Prevention of disease and knowledge of its laws were being attained and he thought would encroach upon the curative part of their profession.

Reviews and Notices of Books.

The Treatment of Injuries by Friction and Movement. By WHARTON P. HOOD, M.D. St. And., M.R.C.S. Eng., L.S.A., Honorary Surgeon to the Royal Academy of Music, &c. London: Macmillan and Co. 1903. Small 8vo, pp. 182. Price 4*s.* 6*d.*

JUST a third of a century has passed away since Dr. Wharton P. Hood contributed to our columns and afterwards published in book form a series of papers on Bonesetting, in which he explained to the medical profession the nature of the manipulations then customarily practised by the persons who assumed the title of "bone-setters" and whose use and wont it was to deal with cases, at that time unfortunately only too common, in which a period of unduly prolonged rest after what might at first appear to be only a trivial injury had been followed by some form of permanent disability. Dr. Hood showed that these cases were, as a rule, examples of spurious ankylosis combined with muscular wasting, and explained not only the nature of the manipulations by which they were frequently cured but also the safety and advantage with which these manipulations could be conducted under the guidance of adequate anatomical and surgical knowledge. It was well known at the time that the so-called "bone-setters" frequently inflicted serious injuries upon persons who came under their hands and also that members of the fraternity had been successful in cases which had resisted the treatment of the most skilful surgeons—cases some of which had been rendered almost notorious by the rank or position of the patients. In commenting upon Dr. Hood's papers when they first appeared we expressed the opinion that they were calculated to inflict a death-blow upon a form of quackery which had rested upon a neglected or forgotten truth; and said that the author had called attention to morbid conditions which had been only very faintly described in books and scarcely at all recognised in practice, as well as to methods of cure at once simple and intelligible. Manipulations analogous to those of the "bone-setter" were at that time often required in practice; and, in the hands of a good surgeon, would be applied to none but suitable cases and under precautions which removed all danger of injurious consequences.

In the little book which, after the lapse of so long a period, Dr. Hood has recently given to the profession he reviews the results of an experience of old and recent injuries which extends, he tells us, to 23,500 separate cases, and relates the results of his attempts so to modify early treatment as to prevent the occurrence of those crippled conditions which in his first publication he showed the way to cure He tells us that during the first few years after the publication of his book on bone-setting he was naturally called upon to see old injuries in larger proportions than recent ones, but that before long cases of the latter kind came under his notice with sufficient frequency to call for complete reconsideration of the methods commonly employed in dealing with them. He points out that an approach to his methods which he began to practise 20 years ago was advocated in 1895 by Dr. J. Lucas-Championnière, and still more recently by several English surgeons, but he doubts whether any of these gentlemen admit his view of the physiological principles on which the treatment should depend or the extent to which friction and early movements of the affected part should be carried. On all these points as well as on the actual conditions of sprains and of ruptured muscular fibres, and on the methods by which such injuries may be prevented from becoming causes of prolonged disability, Dr. Hood writes with great clearness; but so concisely and with so complete an absence of superfluous verbiage as to render quotation extremely difficult. We can cordially recommend his work to the attention of every practitioner who is liable to be called upon to deal with injuries, especially with injuries of the class likely to arise from the modern practice of athletics; and we believe that very few readers will either be inclined to lay it aside until they have finished it or will fail to obtain valuable practical suggestions from its pages.

The Refraction and Motility of the Eye. For Students and Practitioners. By WILLIAM NORWOOD SUTER, M.D., Assistant Surgeon to the Episcopal Eye, Ear, and Throat Hospital, Washington, D.C. Illustrated with 101 engravings in the text and four plates in colours and monochrome. London: Sidney Appleton. 1904. Small 8vo, pp. 390. Price 9*s.* net.

THE work is divided into four parts, the first part treating of the theory of refraction; the second describing the refraction and motility of the normal eye; the third giving an account of the methods of determining the refraction of an eye with their application to cases of hypermetropia, myopia, and astigmatism, with a chapter on anisometropia and upon presbyopia and anomalies of accommodation; and the fourth part dealing with disorders of motility which are considered under the two heads of non-paralytic disorders of muscular equilibrium and paralytic disorders of motility. Into a comparatively small space Dr. Suter has compressed a large quantity of information, and although owing to the number of books dealing with the refraction of the eye it is difficult to state in other language than such as is to be found in the ordinary text-books on optics the essential facts of the reflection and refraction of light, the change of direction impressed upon luminous rays by lenses and prisms, and the course pursued by such rays through the media of the eye under conditions which lead to the formation of a normal or distorted image of the external world, yet Dr. Suter manages to give a certain freshness to his expositions, whilst his familiarity with the subject enables him to form and to express his opinion upon disputed points. Thus, to take one example only, in regard to the rival theories of Helmholtz and Tscherning upon the nature of the accommodation of the eye to objects at different distances which has been the subject of much discussion and still divides the opinions of experts, he supports Helmholtz's views, remarking that "the diminution of spherical aberration which occurs in accommodation, as shown by Tscherning, is a direct sequence of the peripherally diminishing curvature and consequently it is not inconsistent with Helmholtz's theory. As regards Tscherning's experiments upon the eyes of animals it should be noted that traction made upon the suspensory ligament can cause increase of curvature at the summit only when the lens has a hard nucleus surrounded by soft cortical matter as may be found in the lens of the adult ox, the animal upon which Tscherning's examinations were made. In the lens of the calf traction causes flattening at the summits of the surfaces. It is evident, therefore, that Tscherning's experiments do not substantiate his theory, for the solid nucleus which is necessary (as admitted by Tscherning) in order that traction may cause an increase of curvature does not exist in childhood—the period of greatest accommodative activity"—a very sound argument and conclusion.

The methods of determining the refraction of an eye are fully described. These are divided into subjective and objective methods, the former including those in which optometers are employed, some of which are based on the action of a convex lens, others on the principle of the opera glass, others on Scheiner's experiment, others on the property of chromatic aberration, others on the measurement of the retinal diffusion-circles, others on the movement of the diffusion-image on the retina, and others based upon visual acuteness and its assistance when defective by means of lenses. The objective methods include the determination of the refraction of the eye by the direct and indirect methods of ophthalmoscopy, by skiascopy, and by keratometry. In each instance Dr. Suter explains the mode in which the test is applied, as well as in many instances the advantages and disadvantages of the test, in actual practice. We have mentioned these tests to show how carefully this ground has been worked over, especially in America, and to indicate to the student how large is the field on which he is entering in commencing the study of the diseases of the eye when so much is to be learnt on the subject of refraction alone. The fourth part of the book devoted to squint is carefully and clearly written; the various methods of tenotomy and of advancement of the tendon of the *rectus* muscle are well explained and illustrated. We recommend Dr. Suter's work as an excellent *résumé*, without being too abstruse, of the present state of our knowledge of the normal and the abnormal refraction of the eye.

Mrs. Piper and the Society for Psychical Research. Translated and slightly abridged from the French of M. SAGE by NORALIE ROBERTSON, with a Preface by Sir OLIVER LODGE. London: R. Brimley Johnson. 1903. Pp. xviii.-187. Price 3*s*. 6*d*. net.

IT is not very easy to determine what should be done by the critic in the case of a book of this description. To ignore it entirely is not wise, because if this be done it is said that the medical profession know nothing about certain strange mental phenomena and decline to be taught by people who devote their time and abilities, such as they are, to the investigation of these things. If, again, such a book as this be dismissed, as it positively deserves, with a brief sentence it may be thought that no study has been devoted to it or that it opens a new world at which the medical mind shrinks back aghast and tries to disguise its wonder by a passing jest. If a still different course be taken and the work be discussed as a serious contribution to mental science the medical reader would, for his part, have real cause for complaint.

The claims which this little volume has for passing notice are two. In the first place it contains an introduction by Sir Oliver Lodge and in the second it will serve to show the general reader in a few words the curious position taken up by the friends of Mrs. Piper and will enable him to form his own opinion on the deductions and inferences which they make from the observed phenomena, if it be granted that a correct account has been given of the latter. Sir Oliver Lodge's introduction is a little apologetic. He had consented to write the preface "with some misgivings" before he saw the book and "now that I see it in its English dress," he adds, "I find my misgivings justified." However, the author, M. Sage, he says, speaks deprecatingly of his purpose in writing it and calls it "un modeste ouvrage de vulgarisation," and from this point of view Sir Oliver Lodge considers it successful. He goes on to say that he wishes to guard himself from any endorsement of the sentiments and comments of M. Sage, and these appeared to him "less appropriate" when they were translated, although "as they were intended in the original they were not out of keeping." This it must be admitted is not an easy argument to follow but we may take it that Sir Oliver Lodge considers the book a fair one so far as Mrs. Piper is concerned and that it will tend to the popularisation (vulgarisation) of her work.

Mrs. Piper is the wife of an American shopman, is of a home-loving disposition, of little education, commonplace, "sometimes even trivial" in her conversation, and her personality is attractive. She came to England and Professor Charles Richet had a sitting with her; she went into a "trance," her voice changed, and, lo! "she is no longer Mrs. Piper but Dr. Phinuit who speaks in a loud masculine voice in a mingling of negro patois, French, and American dialect." M. Sage explains that the Phinuit personality is what spiritualists call "a control," that by control is meant the mysterious being who is supposed to have taken possession of the organism of the medium, and he asks whether the controls are only "secondary personalities" or "disincarnated human spirits." Without answering his own question he says, "in either case they must have a name." Now, on this point we are inclined to join issue. Is there any reason why Mrs. Piper in the circumstances described shall not keep her own name? We need not follow the career of Dr. Piper Phinuit in detail and habitual readers of this sort of literature know what to expect. They will be pleased to come across their old friend Stainton Moses who had, at the time he was sent for, been about three years "in the spirit." We doubt if the scientific side of psychical research is well served by the publication of this book.

Infant Feeding. By LOUIS FISCHER, M.D. Third edition. With 54 illustrations. *Philadelphia: F. A. Davis Co.* 1903. Pp. 357. Price $1.50 net.

A PARALLEL reading of this edition and of the one which preceded it by no means convinces us that Dr. Louis Fischer has effected any genuine improvements in his work on infant feeding. It is true that he has modified certain of his views, notably on laboratory milk and on the value of Gaertner's milk, and has introduced generally more accuracy and precision into his methods, but the subject matter is so badly arranged and consists to so disproportionate an extent of quotations which are borrowed from other authors that it is impossible to regard this edition at all events as anything beyond a compilation, and not a very satisfactory one at that. It is difficult to suggest a reason for many of these literary plagiarisms; for instance, considerable space is devoted to quotations which would certainly discredit the use of such old nursery friends as lime water, bicarbonate of soda, and sugar of milk, if they could be taken seriously, and yet in face of the prominence which is given to these somewhat startling pronouncements we find in other sections of the book that the use of these commodities is warmly advocated. We only mention these seeming contradictions, which are unimportant in themselves, as illustrations of the general want of consistency which so markedly detracts from the merits of Dr. Fischer's book as a practical guide to the feeding of infants. It is difficult to determine which, if any, of the many artificial methods described in these pages is the one which Dr. Fischer recommends for the ordinary routine feeding of infants. He claims, however, that Coit's decimal method is the simplest and most easily applied system for the home modification of milk. For this method three solutions are required—a 10 per cent. cream, a 10 per cent. saccharated skimmed milk, and a 10 per cent. solution of sugar. By combining these solutions in various proportions milk mixtures of various percentage composition may be obtained. The method does not appear to us quite as simple as Dr. Fischer would have us believe; indeed, the mathematical calculations which are involved in the working out of the formulæ strike us as particularly complicated. The method has, however, the extreme advantage of being a scientific one and one which, though perhaps never absolutely exact, possesses only a small margin of possible error. Two chapters which are devoted to the subjects of milk substitutes and milk idiosyncracies in children deal respectively with two most important and difficult problems. Both of these chapters contain some very useful hints although neither of them can be regarded as complete solutions to the questions involved. In speaking of the unpopularity in certain quarters of milk laboratories and their methods, the author regards it as possible that certain of the unsatisfactory results which have been noted may be due to the overheating of the milk. He urges, therefore, that those who employ these laboratories should insist upon "having the formulæ compounded by using raw milk and fresh cream"; the natural living qualities of the milk may thereby be preserved thus rendering it more assimilable than when it has been subjected to prolonged heating. He anticipates that if this simple precaution be taken even the strongest opponents of this method may yet be convinced of the superior advantages of milk which has been handled and modified with the care which is usually bestowed upon it at milk laboratories. We notice on p. 140 the curious statement that glycerine is "an oil," and as such indicated in children requiring fat; and we further notice that this "oil" is recommended to be injected to the amount of five ounces mixed with 20 ounces of warm water into the infant's rectum when suffering from constipation. Apart from the heroism of this proceeding, it strikes us as one which would be rather expensive for routine or hospital practice. As will have been gathered from the preceding remarks we do not regard Dr. Fischer's book as a good one on the subject of infant feeding. It is controversial without being critical and, although it contains an immense amount of sound information, the information is so badly arranged that it ceases to be instructive.

A Text book of Pathology. By ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania; Physician to the Philadelphia Hospital. With 394 illustrations in the text, many of them in colours, and seven full-page chromolithographic plates. Fourth edition, thoroughly revised. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 933 Price 21*s*.

IN reviewing a work that has reached a fourth edition but little need be said as to its general nature and scope. Dr. Stengel has endeavoured to continue to present the subject of pathology in as practical a form as possible and always from the point of view of the clinical pathologist. He has succeeded in his design in a most admirable manner. In the preface to the present edition Dr. Stengel remarks that its preparation has been rendered difficult by the mass of important work that has appeared in the last two or three years. We can fully appreciate the embarrassments which he encountered. During that period an immense amount of work in pathological investigation has been accomplished. Dr. Stengel, however, has constantly kept before him the necessity of incorporating only demonstrated facts and avoiding unproved hypotheses. In thus acting he has done wisely. It is very confusing to the student to be presented with theories and suggestions on abstruse subjects none of which has definitely been proved to be correct. Such discoveries may be interesting to an expert but are useless for purposes of instruction. The section of the book dealing with general pathology has required the greatest care and has been most extensively revised, several of the important chapters having been practically rewritten. Ehrlich's theories of immunity and allied processes are fully considered and explained in as lucid terms as such an involved subject will permit. Dr. Stengel is of opinion that "Ehrlich's side-chain theory" explains the facts regarding the action of toxins and the formation of antitoxins better than any that has been suggested and he further adds that all the steps in this theory have been practically demonstrated. The chapter on inflammation has received close attention and now contains a *résumé* of the latest investigations on the subject. In discussing typhoid fever attention is drawn to the fact that local or general typhoid infection may occur without the intestinal lesions or usual clinical features of typhoid fever. In such cases local inflammatory lesions, suppurations or necroses, or septicæmia have been observed. A short description is also given of paracolon or paratyphoid infection. Cases have been reported resembling typhoid fever clinically but in which the Widal reaction was persistently absent and in which bacilli closely resembling the typhoid or colon bacillus, though differing in some essential particulars, were isolated from the blood and tissues. Dr. Stengel asserts that the bacilli differ from the bacillus of typhoid fever by their ability to produce gas in glucose-containing media and to produce alkali in nutrient media. They differ from the bacillus coli communis by not coagulating milk, by not fermenting lactose, and by failing to form indol. The remarks on tuberculosis have been carefully arranged so as to include most of the latest researches. The relation of human to animal tuberculosis, however, is only briefly touched upon. A short description is given of the smegma and other acid-proof bacilli. The etiology of yellow fever is discussed. The experiments of Reed and Carroll naturally receive notice, for these observers demonstrated the importance of mosquitoes as agents in the transmission of the disease. It was definitely proved that a special form of mosquito—the stegomyia fasciata—carries the contagion from one person to another. The bacillus icteroides, discovered in 1897 by Sanarelli, seems to be a secondary invader and not the cause of the disease.

The second half of the book (on Special Pathology) has been also subjected to considerable revision, although extensive alterations have not been so necessary as in the first portion of the work. The chapter on Diseases of the Blood has been brought up to modern requirements. A classification of the varieties of leucocytes is exceedingly difficult as transitional forms are abundant. The classification introduced by Ehrlich and his pupils is here adopted and while it is not entirely satisfactory it has one advantage over others—viz., that it is comparatively simple. The pathological changes occurring in the red corpuscles are also described. Investigations into the properties and alterations of the erythrocytes have necessitated the introduction of some new terms, such as "anisocytosis" and "hemokiniæ," which in due time will become familiar. A few observations are also made on the pathological changes in the plasma. These are mainly of a chemical character and consist of the presence of abnormal substances or of normal constituents in excessive quantity. A chapter has been added on the Technique of Pathological Methods. We must conclude with a few words of congratulation with regard to the illustrations. They are admirable. In this edition many of the old ones have been replaced by new and a number of plates have been added where more ample illustration has seemed advisable. We may draw especial attention to the plates illustrating the diseases of the spinal cord which are beautifully executed.

LIBRARY TABLE.

The Practical Care of the Baby. By THERON WENDELL KILMER, M.D. Philadelphia: F. A. Davis Co. 1903. Pp. 158, with 68 Illustrations. Price $1.—This little book adds one more to the list of works on the care of infants which owe their authorship to a member of the staff of the Baby's Hospital in New York. Evidently no trouble or expense has been spared to make it a thoroughly attractive book. It is lavishly provided with excellent illustrations, printed in large type and we imagine in every way suitable for young mothers who "know absolutely nothing about the care of a baby." A considerable amount of space —we are inclined to think a rather disproportionate amount—is devoted to the description and illustration of babies' and children's clothing. The directions for feeding, which is always the most important feature in a book of this kind, are taken from Dr. Emmett Holt's "Care and Feeding of Infants"—not, however, from the last edition of that little work but from one of the earlier issues. This, in our opinion, shows a wise discrimination, for the method which Dr. Holt first advised is altogether simpler and more practical than the system he now suggests. There has been pressed into a comparatively small space an immense amount of information on such subjects as airing, exercise, sleep, teething, the condition of the bowels, increase in weight, and a host of other matters about which even mothers of large families often remain ignorant to the end. About one-third of the volume is given up to the consideration of minor ailments and emergencies, with full instructions as to what to do should such arise. In every respect we regard "The Practical Care of the Baby" as a most excellent little book.

The Knights Hospitallers in Scotland and their Priory at Torphichen. By GEORGE THOMAS BEATSON, M.D Edin., C B. *Citizen* Office, Glasgow: James Hedderwick and Sons. 1903. Pp 33. Price 2*s*. 6*d*. net.—Dr. Beatson is the chairman of the Council of the St. Andrew's Ambulance Association and the question arose as to whether this association should affiliate with the Order of St. John of Jerusalem. Dr. Beatson therefore compiled a paper upon the history of the latter order in Scotland and read it before a meeting of the St. Andrew's Association which was held in February, 1903 The book before us is the said paper somewhat enlarged. Dr. Beatson commences by giving a description of the origin of the order and refers to the Amalfi merchants as building a hospital in Jerusalem about 620 A.D. That gossipy pilgrim Felix Fabri, in his Evagatorium[1] circa 1480 A.D., gives the date of the foundation of the Amalfi Hospital (Maria de Latina) as in the reign of Charlemagne—i.e., about 800 A.D.—and the date of the Hospital of St. John the Almoner as 1118 Further, he says that the knights were not under the patronage of St. John the Baptist until after they went to Rhodes. Dr. Beatson, however, says that the Jerusalem House was dedicated to the last-named saint We hold no brief for the accuracy of Fabri and doubtless Dr. Beatson has had access to many other documents bearing on the early history of the Order. The Knights went to Scotland by invitation of King David I. and they were an offshoot from the English Langue. They established themselves at Torphichen where they built a preceptory in 1124 A.D. The tower and the two transepts still remain and we are glad to see are cared for by the *present Lord Torphichen.* Within the domain of the preceptory were five sanctuary stones, two of which are still to be seen. The preceptory, like so many other admirable institutions, came to an end at the Reformation, and small wonder too, for the last preceptor was a personal friend of Knox. Dr. Beatson's interesting work concludes with an urgent appeal for union between the Order of St. John of Jerusalem and the St. Andrew's Ambulance Association.

Sayings of K'ung the Master. Selected, with an introduction, by ALLEN UPWARD. London: The Orient Press. 1904. Pp. 50. Price 1*s*. net.—This little book is one of a series, entitled "The Wisdom of the East," which deals more or less with the religion, the philosophy, and the ethical code of Oriental nations. K'ung-fu-Tzee, or K'ung the Master, was Latinised by Western missionaries into Confucius and this teacher is generally said to have been the founder of a religion. According to Mr. Allen Upward he was nothing of the kind but merely a teacher. He refused to discuss the supernatural because he knew nothing about it. Like St. James he considered that faith without works is dead. Though he himself said, "At 50 I knew the decrees of heaven," he contented himself with teaching men how to live on this earth, teaching them partly by precept but mainly by example, and his ideal was good government in the interest and for the happiness of the humble. The selections given are chiefly from the translation of the Analects by Legge.

JOURNALS AND MAGAZINES.

The Practitioner.—The issue of this magazine for May contains some unusually interesting and attractive articles. Dr. Guthrie Rankin writes a philosophical essay upon old age which might be perused with advantage outside of, as well as within, the ranks of the medical profession. Dr. Leonard L. B. Williams contributes an article entitled "Some Aspects of Obesity." Dr. Williams's views upon the efficiency of slow feeding, cold baths, proper limitation of clothing, &c., are sound and well put and the article should be a useful corrective to the many "fads" that are apt to gather round this question of fat. Dr. H. D. Rolleston provides a careful review of recent work on gastric affections, giving the impression that whatever has been written lately in any tongue has not escaped his notice.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F R S, and J. N. LANGLEY, F.R.S. Vol. XXXI., No 2. London: C. J. Clay and Sons. May 3rd, 1904. Price 6*s* 6*d*.—The articles contained in this number are as follows.—1. On the Formation of Prussic Acid by the Oxidation of Albumins, by R. H. Aders Plimmer, D.Sc., Grocers' Company's Research Student. Dr. Plimmer shows that by the oxidation of albumins with Neumann's acid mixture, or after treatment of the products of hydrolysis, or with potassium dichromate and sulphuric acid in suitable proportions prussic acid is formed, but it does not appear to be formed from the oxidation of the amino-acids. 2. On the Histological Changes produced by Injection of Adrenalin Chloride, by W. B. Drummond, M B., C M Edin., with four figures in the text. Dr. Drummond points out that the histological changes observed by him are due to two factors: the first is the influence of adrenalin upon blood pressure and the second its direct toxic action, the former displaying itself in congestion of the viscera and in the occasional presence of hæmorrhages and of serous effusion and the latter exhibited by the changes in the cells of glandular organs and especially of the liver and kidney. 3. Observations on the Influence of Adrenalin Poisoning on the Liver, with special reference to the glycogen, by W. B. Drummond, M.B, C.M. Edin., and D. Noel Paton, M.D. Edin., with two figures in the text. The glycogen, it is shown by these observers, is diminished in acute, but not invariably in chronic, adrenalin poisoning. The lobules in acute adrenalin poisoning frequently show degenerative changes on their central zones. 4. On the Adaptation of the Pancreas, by F. A. Bainbridge, M.B. Cantab., M.R C.P. Lond., Research Scholar of the British Medical Association. Dr. Bainbridge shows that under normal conditions the pancreas of dogs contains no lactase though this substance is contained in extracts of the intestinal mucous membrane. Yet when dogs are fed for two or more weeks on a milk diet their pancreatic juice obtained by means of secretin invariably contains lactase. He believes that lactose acts upon the intestinal mucous membrane, causing it to produce some substance which is carried in the blood-stream to the pancreas, stimulating that gland to form lactase. 5. On the Physiological Action of the Alkaloids of Jaborandi Leaves, by C. R. Marshall, with 19 figures in the text. Mr. Marshall finds that jaborandi leaves contain three alkaloids—pilocarpine, isopilocarpine, and pilocarpidine. Pilocarpine resembles in its action the effects of electricity on the vagus and this action is counteracted by atropine. Isopilocarpine acts like a weak pilocarpine and pilocarpidine produces still weaker but similar effects. 6. On the Innervation of the Ileocolic Sphincter, by T. R. Elliott, Coutts Trotter Student of Trinity College, Cambridge, with nine figures in the text. Mr. Elliott demonstrates that the junction of the small and large intestine is controlled by a muscular sphincter not by a mechanical valve. Stimulation of the sympathetic causes the sphincter to contract but inhibits the circular muscle in the wall of the ileum and the colon. In the cat the constrictor fibres issue chiefly from the thirteenth thoracic and first and second lumbar roots. This number also contains the Proceedings of the Physiological Society for March.

[1] Hassler's edition, Stuttgart, 1843, vol. ii., pp. 246 and 274.

The British Journal of Children's Diseases. No. 1, Vol. I. London: Adlard and Son. Price 1*s.*—The impetus which has been imparted to the progress of pediatrics in this country by the active operations of the Society for the Study of Diseases in Children has rendered the occasion opportune for the publication of a journal which is exclusively devoted to this important branch of medicine. The first number of the *British Journal of Children's Diseases* was published in January of this year and will continue to appear monthly under the editorship of Dr. George Carpenter. It is practically certain that a journal conducted on the lines which are foreshadowed in the first number will be actively supported by a large and increasing number of readers. The first number contains several excellent original articles, notably by Dr. James Taylor on a case of Hemicrania, by Dr. Edmund Cautley on Congenital Stenosis of the Pylorus, by Mr. Clinton T. Dent on the same subject, by Dr. G. A. Sutherland on Intussusception and Henoch's Purpura, and by Mr. T. Glenton-Kerr on the Administration of Children's Hospitals. The number also contains under the title of "Excerpta Puerilia" a number of miscellaneous notes on matters in the domain of pediatrics which will be of general interest.

New Inventions.

A NEW BEDSIDE SPITTOON.

IN the ordinary earthenware bedside spittoon with a loose funnel some of the sputum usually dries on the latter and becomes a source of danger in addition to presenting an unsightly appearance. The chief objection to the forms with hinged lids is the difficulty of keeping them clean, for sputum lodges and dries in the hinge which is speedily destroyed if attempts are made to sterilise the spittoon by boiling. The various spittoons with loose paper or card linings are advisable but their cost prevents their extensive use in hospital practice. Whilst resident medical officer at the Mount Vernon Hospital for Consumption at Hampstead I designed a bedside spittoon which has been made by Messrs. Allen and Hanburys of 48, Wigmore street, London, W., and has been in use at the hospital for some months. It is strong, being made of enamelled iron, and is not unsightly. It is also cheap (12*s.* 6*d* per dozen) and easily kept aseptic as it is not injured by boiling and it has no crevices in which sputum can lodge.

FIG. 1.

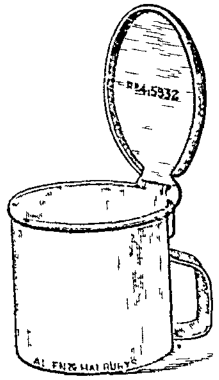

FIG. 2.

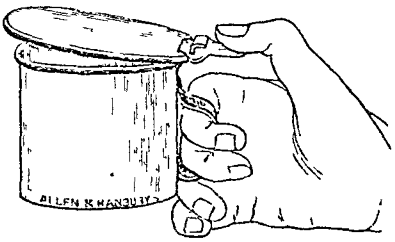

As will be seen from the illustrations the handle is placed lower down than is usual and from the rim above it a small curved projection passes backward and engages in a small slit in the lid, forming an efficient hinge. The lid is easily removed and is opened by pressing on its projecting process when raising the cup.

SYDNEY R. WILLIAMS, M.R.C.S. Eng., L.R.C.P. Lond.
Fishponds, Bristol.

Looking Back.

FROM

THE LANCET, *SATURDAY,* May 20, 1826.

NOW the whole of the *alimentary canal,* (like the *air-passages,*) is lined by a *mucous membrane,* which is subject to the affections that belong to this kind of structure in general; namely, inflammation, with its consequences, and which has received different names, according to the particular part it occupies. These, which are mere *varieties,* have been considered as different *species* of disease; although, pathologically considered, they are essentially the same, and require a treatment, in all essential points alike, doubtless with some modifications, arising out of their relative connexion with other parts. We have no general term in common use like that of catarrh to express an inflammation of the lining membrane of the alimentary canal altogether; but the affections of particular parts of it, have had *specific* names given to them. Thus, when that part of the mucous membrane which lines the mouth, is affected with inflammation, it constitutes the disease termed *aphtha,* or the *thrush.* When the fauces are similarly affected, the disease is termed *cynanche* or *angina;* in common language, the *sore throat* or quinzy.

In the œsophagus and stomach, the affection is termed *cardialgia* or *heart-burn,* in the small intestines, *diarrhœa;* in the large intestines, *dysentery.* And when the whole alimentary canal is at once similarly affected, the disease has been termed *cholera morbus.*[1]

[1] Excerpt from lecture on the Theory and Practice of Physic, delivered by Dr. Clutterbuck in the theatre, General Dispensary, Aldersgate street.

NATIONAL SANATORIUM FOR CONSUMPTION, BOURNEMOUTH.—The annual general meeting of governors of this charitable institution was held in London on May 12th at the Westminster Palace Hotel, the Right Hon. Arthur F. Jeffreys, M.P., occupying the chair. The annual report of the committee of management for the year 1903, which was unanimously adopted, stated that the accounts showed a deficiency of £305, as compared with a deficit of £540 the previous year. As a result of the special appeal the annual subscriptions showed an increase of £139 and donations an increase of £514. The committee regretted that the annual subscriptions did not show a larger increase, as the income was still insufficient to meet the current expenditure. It desired particularly to add that by the additional accommodation which is being provided new annual subscriptions to the amount of at least £500 were urgently needed. During the year 225 patients were admitted, of whom 182 were discharged improved, many being fitted to return to their occupations. 64 patients were continued from 1902, so that the total number under treatment last year was 289. The average length of stay in the sanatorium was 11·8 weeks. Mr. Robson-Burrows, a member of the committee of management, informed the meeting that the plans and specifications for the new extension of the sanatorium had been prepared and that tenders were being invited for carrying out the work.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1904.

The Future of Medical Education in London.

THE oration by Sir ISAMBARD OWEN before the Medical Society of London, which we publish at p. 1399 of this issue, was peculiarly appropriate at a time when on all hands it is admitted that medical education is passing through a trying period of transition. Although many look hopefully to the future when all difficulties shall be smoothed away, others feel a certain degree of anxiety lest the schemes upon which reliance has been placed may never be carried into effect or may so far revolutionise medical teaching that disastrous consequences may ensue. Sir ISAMBARD OWEN commenced his oration with a pithy anecdote to demonstrate the lack of general interest in science exhibited in this metropolis as compared with continental cities, and there can be no doubt that in London we are so accustomed to the modesty of our greatest men of science that when living they pass unnoticed in the street, and when dead their names are only gratefully remembered by their fellow workers. The desirability of erecting statues or other memorials does not occur to their followers who hold that their masters still live in the memory of their work, while money may be better spent in advancing science or in alleviating distress. Different nations have different methods of expressing appreciation. This, however, formed only the introduction of Sir ISAMBARD OWEN'S argument. His chief contention was that, as compared with other nations, there is in this country a lamentable lack of public interest in education. Considering that the political atmosphere has recently been so much agitated on this very subject it is interesting to note that the average Englishman only gets excited about education when it concerns a point of religion. In contrasting the general condition of education in this country with that obtaining abroad most effective use was made of the report of the Mosely Educational Commission to the United States of America, from which can be gathered much that is instructive and much that is depressing. The report is instructive in showing the appreciation of the value of education and the readiness of the State and of private benefactors in the United States to contribute enormous sums to improve what is rightly regarded as an "essential condition of prosperity." It is depressing to us as a nation when, with certain isolated recent examples, the American spirit is contrasted with the grudging spirit with which appeals for educational improvements are regarded in this country.

While this is true of all forms of education, the public apathy is perhaps most marked towards medicine, and we believe Sir ISAMBARD OWEN is right in attributing this to want of knowledge rather than to wilful indifference. To some extent, however, it must undoubtedly be assigned to the spirit of honourable rivalry which has so long existed between the different metropolitan medical schools. This rivalry has led to needless multiplication of teaching institutions and as the character of education has gradually changed so the need of expensive laboratory accommodation has grown. The slow evolution of the London Schools of Medicine is emphasised by Sir ISAMBARD OWEN—it was not born or made but simply "grew spontaneously in response to a need." At the present time the growth has been so great that it is becoming a source of weakness rather than of strength and all concerned in the welfare of London medical education are restlessly awaiting the advent of one or more benefactors. The buildings are there but without a preliminary endowment they cannot become self-supporting. Not long since we referred to the munificent gift of Sir DONALD CURRIE to University College. It will be remembered that before the incorporation of this College as an integral part of the University of London it was necessary to dissociate the hospital and the subjects of clinical study from all financial connexion with University College[1] Sir DONALD CURRIE'S gift provided for the erection of buildings for a school of advanced medical studies connected with the hospital, leaving the subjects of preliminary and intermediate medical study to be taught within the College. Sir ISAMBARD OWEN believes that the division of the curriculum into two nearly separate portions, the one mainly professional and the other purely academic, affords some ground for hope in the future, and he looks to the University of London as a central teaching authority to assist, to lead, or to coordinate the scattered educational agencies. The plan submitted is, however, open to some misunderstanding. What is hoped for is not quite clear. We are told that while London is asleep the provinces are moving and that disaster must follow unless London awakes to some sense of its responsibility. This supposed condition of somnolence, this sleeping sickness, appears only to mean that the best clinical teachers with the best clinical material may, unless some relief is forthcoming, find themselves without anyone to teach. Surely this danger has been painfully impressed for many years by the diminishing entries at the London medical schools. It is not the teachers who need rousing but those from whom it is hoped that endowment may be derived. The teachers realise the position but London appears to be too vast, too cosmopolitan, to take cognisance of the present needs of medical education and of the danger of losing the opportunity of successfully competing with the provincial schools, some of which have received munificent endowments. The solution offered by Sir ISAMBARD OWEN is the speedy establishment as part of the University of London of a public institute of medical sciences to undertake teaching in physics, chemistry, biology, anatomy, and physiology for the purposes of medical students. This scheme has been drawn up by the Faculty of Medicine of the University and officially adopted by the Senate. All that is wanting is to find the funds and these have been estimated at £375,000. The scheme is bold but there is one small danger. In the earlier part of the oration reference is made to the American disposition to "regard buildings and sites as of more importance than men," and this is certainly suggestive. When, if ever, the new public institute is in full work it must inevitably enter into competition with those medical schools which continue to teach the same subjects, and it must also draw its teaching staff from them since previous practical experience is to be desired. The University of London will not follow American example, we trust, in *attaching more importance to the edifice than to the personnel* of the teaching.

---

[1] THE LANCET, March 26th, 1904, p. 880.

The oration deserves thoughtful study, especially in connexion with the words of Mr. A. PEARCE GOULD who, in seconding a vote of thanks, remarked that a public appeal was likely to meet with more ready response if it resulted from the coöperation and fusion of the interests of the medical schools than if made merely to benefit one institution. The public, who may rightly plead weariness of requests to support this or that hospital, may yet come to the rescue in favour of medical education as a whole if the matter is put bravely before them. The whole subject is one of extreme difficulty and must undoubtedly be met in a broad spirit. Sir ISAMBARD OWEN clearly hopes that in the future the various medical schools will be content to receive only those students who have already passed all the subjects of preliminary and intermediate medical study and thus will be freed from the necessity of the present wasteful expenditure on these subjects. The scheme is deserving of support if the creation of a new building and a new organisation under the control of the University of London is really the only means by which an appeal for endowment can be successful. It is impossible, however, to read the admission that the present "buildings of the schools would in the aggregate suffice for the needs of many a renowned university" without feeling regret that they should be superseded and converted to other uses.

A Russian Medical Man on Medical Practice.

A LITTLE while ago we devoted a leading article to the consideration of private practice as it appeared in a novel, the central figure of which was a general practitioner in a country town of Germany.[1] A Russian book translated into English under the title of "The Confessions of a Physician" attracts us again to view a very similar subject. Here, however, the field is perhaps a wider one, for it is rather medical practice as a whole and the ethical position of a medical man in the community at large than the trials of any particular branch of the profession that the Russian author takes for his theme. If the German's book produced an impression that was on the whole painful and discouraging his Russian colleague is able to provide us with no more cheerful aspect of medical practice. Much must be allowed for the obviously morbid and too sensitively introspective nature of the author himself. He is conscientious, scrupulous, and self-accusing to the last degree and suffers acutely for mistakes which, if they had happened to others, he would have been ready to pardon and to explain. Moreover, he describes accurately scenes and actions which, though a necessary part of medical practice both in and out of hospitals, yet in their description may lay the author open to the charge of grossness. We by no means proffer this charge, yet we regard certain passages in this book as rendering it entirely unfit for the perusal of the non-medical reader.

To the medical man the author appeals by his obvious sincerity and by his determination to omit nothing, whether discreditable to himself or the reverse, of the impressions which were made upon him from the first days when he began his professional studies. In these days, as a young man is apt to be, he was overwhelmed by the material side of things, coming to the facts as science revealed them and incapable as yet of realising a spiritual aspect even to that which is apparently merely gross. Thus his anatomical studies distorted for him all human creatures. "People who were near and dear to me assumed a dual quality: that young girl, for instance—there is so much originality and attractiveness about her! When in her presence I feel happy and light of heart, but at the same time all that goes to make her is well known to me and there is really nothing extraordinary about her; her brain is corrugated by the same convolutions such as I have seen upon hundreds of brains; her muscles are permeated through and through with fat which makes the dissection of feminine corpses such an unpleasant task; in a word, there is nothing in her either attractive or suggestive of poetry." At this stage of his career he is surprised, shocked, and depressed by the moral agonies to which he thinks female patients must often be exposed by examination in hospitals. Here the English reader will find his sympathy but little stirred for if VERESAEFF'S account be true then there must be in Russian hospitals a great want of that consideration and careful decency which, we are glad to know, obtain generally in the teaching of gynæcology in this country. Advancing a little further along the path of medical study our author now is almost driven to despair by realising how many conditions there are for which even the most enlightened medicine and surgery can offer no relief. His anger is like that of the uninstructed son who declares all medical men useless because his father is dying from malignant disease. Such anger might with equal reason be directed against nature herself. It would be as sensible to revile Omnipotence for permitting such diseases as medicine for being incapable of curing them. Medicine does not claim infallibility or omnipotence. Ignorance thrusts these upon her shoulders and then raves when medical science does not rise to performances which she never claimed to achieve. VERESAEFF, of course, with further study, is reconciled by the sight of how very much medicine and surgery *can* do to the thought of the large amount which they still cannot. With regard to the examinations which complete his curriculum as a student and allow him to pass into the world as a qualified practitioner, the Russian author makes some scathing comments which are applicable in other countries besides his own. He objects to the theoretical as opposed to the practical value of the tests and concludes that "if you were to subject after the lapse of five years a fully fledged doctor to the same ordeal, without previous warning, he would fail ignominiously. ...... Not a single eminent physician would be able to pass his examination a second time without laborious preparation unless his inquisitors showed leniency
